Exercise 15: Spinor algebra (P) *(1+2+3+2+3 = 11 points)*

We want to examine the underlying algebra of fermionic structures. We consider the spinors

$$u(\vec{p}, s) = \sqrt{p_0 + m} \begin{pmatrix} \varphi_s \\ \frac{\vec{\sigma} \cdot \vec{p}}{p_0 + m} \varphi_s \end{pmatrix} \qquad v(\vec{p}, s) = \sqrt{p_0 + m} \begin{pmatrix} \frac{\vec{\sigma} \cdot \vec{p}}{p_0 + m} \varphi_s \\ \varphi_s \end{pmatrix}$$

where $s \in \{-\frac{1}{2}, \frac{1}{2}\}$, $\vec{\sigma}$ was given in exercise 1 and

$$\varphi_{\pm 1/2} = \begin{pmatrix} 1 \\ 0 \end{pmatrix} , \qquad \varphi_{\mp 1/2} = \begin{pmatrix} 0 \\ 1 \end{pmatrix} , \qquad p_0 = \sqrt{m^2 + \vec{p}^2} ,$$

where the upper sign applies for u and the lower sign for v.

(a) Prove that

$$(\vec{\sigma} \cdot \vec{p}) (\vec{\sigma} \cdot \vec{p}) = \vec{p}^2 1_{2 \times 2} .$$

(b) By using the explicit Dirac representation of the Dirac matrices (cf. exercise 1), prove that the spinors u and v are solutions to the Dirac equations

$$(\not{p} - m)u(\vec{p}) = 0 ,$$
$$(\not{p} + m)v(\vec{p}) = 0 .$$

(c) Prove the following orthogonality relations for the spinors u and v:

$$u^\dagger(\vec{p}, s)u(\vec{p}, s') = 2p_0 \delta_{ss'} , \quad v^\dagger(\vec{p}, s)v(\vec{p}, s') = 2p_0 \delta_{ss'} ,$$
$$u^\dagger(\vec{p}, s)v(-\vec{p}, s') = 0 , \quad v^\dagger(\vec{p}, s)u(-\vec{p}, s') = 0 ,$$
$$\overline{u}(\vec{p}, s)u(\vec{p}, s') = 2m \delta_{ss'} , \quad \overline{v}(\vec{p}, s)v(\vec{p}, s') = -2m \delta_{ss'} ,$$
$$\overline{u}(\vec{p}, s)v(\vec{p}, s') = 0 , \quad \overline{v}(\vec{p}, s)u(\vec{p}, s') = 0 .$$

where $\overline{u} = u^\dagger \gamma^0$ and $\overline{v} = v^\dagger \gamma^0$.
Hint: Use γ^0 in the explicit Dirac representation.

(d) Prove the following completeness relations of the spinors u and v,

$$\sum_{s=-1/2}^{+1/2} u_\alpha(\vec{p}, s)\bar{u}_\beta(\vec{p}, s) = (\not{p} + m)_{\alpha\beta},$$

$$\sum_{s=-1/2}^{+1/2} v_\alpha(\vec{p}, s)\bar{v}_\beta(\vec{p}, s) = (\not{p} - m)_{\alpha\beta},$$

where α and β are indices in spin space.

Remark: These relations, also called *spin sums*, are very useful for practical calculations of fermionic scattering processes later on.

(e) Prove the *Gordon identities* for the spinor u,

$$0 = \bar{u}(p)[(p - q)^\mu + i\sigma^{\mu\nu}(p + q)_\nu]u(q),$$

$$\bar{u}(p)\gamma^\mu u(q) = \frac{1}{2m}\bar{u}(p)[(p + q)^\mu + i\sigma^{\mu\nu}(p - q)_\nu]u(q),$$

$$\bar{u}(p)\gamma^\mu\gamma^5 u(q) = \frac{1}{2m}\bar{u}(p)[(p - q)^\mu\gamma^5 + i\sigma^{\mu\nu}(p + q)_\nu\gamma^5]u(q),$$

where $\sigma^{\mu\nu} = \frac{i}{2}[\gamma^\mu, \gamma^\nu]$, purely algebraically, i.e. without using the explicit representation of u given above.

Hint: Use the Dirac equations.

Exercise 16:   Quantization of the fermionic field (P)   (*3+3+3 = 9 points*)

We can now describe a fermionic field $\psi(x)$ as

$$\psi(x) = \sum_{s=-1/2}^{+1/2} \psi_s(x) = \int d\tilde{k} \sum_{s=-1/2}^{+1/2} \left[a_s(\vec{k})u(\vec{k}, s)e^{-ik\cdot x} + b_s^\dagger(\vec{k})v(\vec{k}, s)e^{ik\cdot x}\right].$$

(a) The Lagrangian of a free fermionic field is invariant under a $U(1)$ transformation $\psi(x) \to e^{i\alpha(x)}\psi(x)$. The Noether charge Q associated to this symmetry is given by

$$Q = \int d^3x\, \bar{\psi}\gamma^0\psi.$$

Express Q through the operators $a, a^\dagger, b, b^\dagger$ and interpret the results.

(b) By using the anti-commutators of $a, a^\dagger, b, b^\dagger$, calculate the anti-commutator $\{\psi_r(\vec{x}, t), \psi_s^\dagger(\vec{y}, t)\}$. What is the physical meaning of the fields $\psi^\dagger$ and ψ?

We now consider a coupling of fermions to a photon field. Through the minimal coupling by means of the covariant derivative $\slashed{D} = \slashed{\partial} + iq\slashed{A}$, the Dirac equation becomes

$$(i\slashed{D} - m)\psi = 0.$$

(c) Prove that in the non-relativistic limit, i.e. for $|\vec{p}| \ll m$, this equation transforms to the *Pauli equation* given by

$$i\partial_t \rho = \left[\left(\frac{\vec{\pi}^2}{2m} + q\varphi \right) - \vec{\mu} \cdot \vec{B} \right] \rho,$$

with the magnetic moment being $\vec{\mu} = g\frac{q}{2m}\vec{S}$, where $g = 2$ is the gyromagnetic factor, $\vec{B} = \vec{\nabla} \times \vec{A}$ is the magnetic field, $\vec{\pi} = \vec{p} - q\vec{A}$ is the canonical momentum and $\vec{S} = \frac{\vec{\sigma}}{2}$ is the spin operator.

Hint: Use the ansatz $\psi = e^{-ip \cdot x} \begin{pmatrix} \rho \\ \chi \end{pmatrix}$ for the spinor to split the Dirac equation into two equations for the up-type and down-type spinor ρ and χ, respectively. In the non-relativistic limit, argue why χ is heavily suppressed compared to ρ, which allows you to use $(i\partial_t - q\varphi)\chi \approx 0$ in the system of the two equations.
