Measuring Supersymmetry

Michael Rauch

(in collaboration with Rémi Lafaye, Tilman Plehn, Dirk Zerwas)

arXiv:0709.3985 [hep-ph]

Outline

- Supersymmetry
- Current Status
- Determining SUSY Parameters
- Kinematic Edges as Experimental Input
- Possible Collider Results
- Testing Unification

Supersymmetry

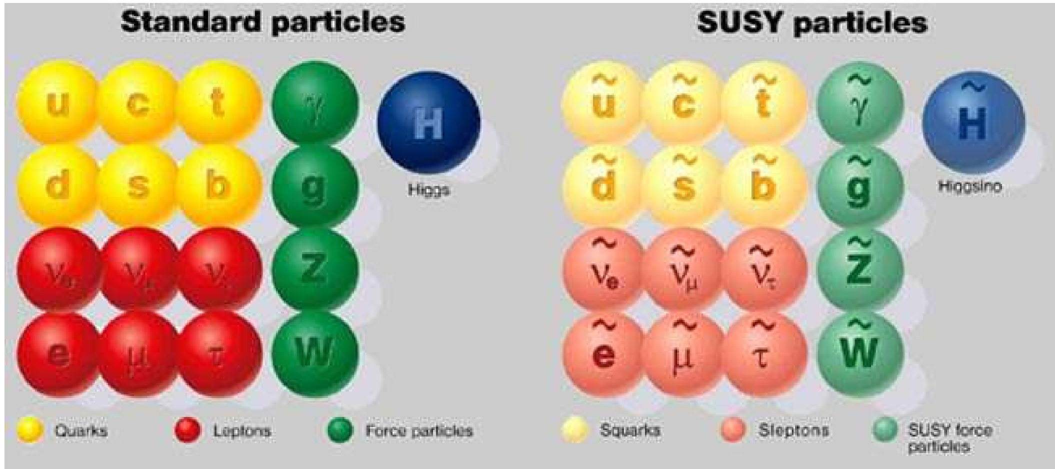
Symmetry between bosons and fermions:

$$Q\,|\text{boson}\rangle = |\text{fermion}\rangle\,; \qquad Q\,|\text{fermion}\rangle = |\text{boson}\rangle$$

Q: Supersymmetry Operator

Simplest model:
Minimal Supersymmetric Standard Model (MSSM)

- Supersymmetric partner to each Standard Model particle
- Two Higgs doublets ⇒ 5 Higgs bosons (h^0,H^0,A^0,$H^\pm$)
- Particles with same quantum numbers mix
  (e.g. Zino, Photino, 2 Higgsino → 4 Neutralino)



mSUGRA

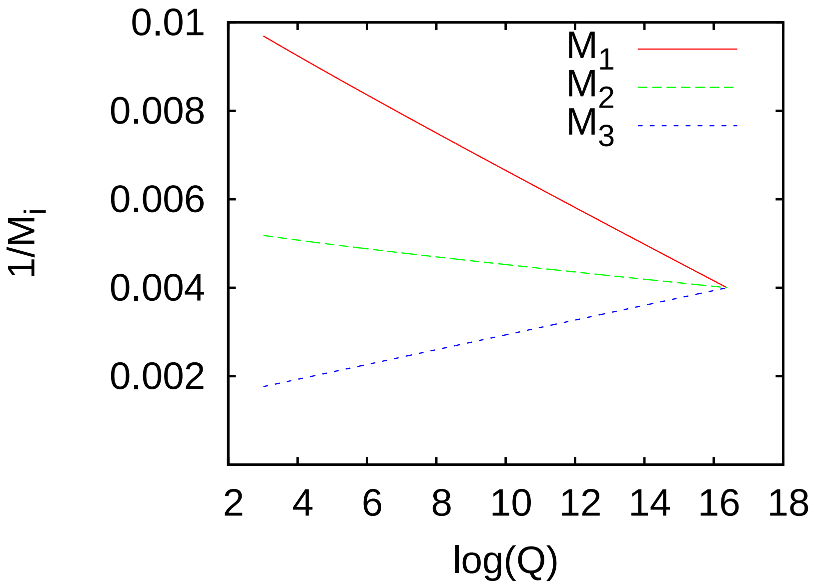
Unification at the GUT scale ($\sim 10^{16}$ GeV):

- Apparent unification of gauge couplings (general feature of MSSM)
- Common scalar mass: m_0
- Common sfermion mass: $m_{1/2}$
- Common trilinear coupling: A_0

plus

- ratio of the Higgs vacuum expectation values at the electro-weak scale: $\tan\beta = \frac{v_2}{v_1}$
- one sign: $\operatorname{sgn}\mu$

Evolve three parameters defined at the GUT scale via renormalisation group equations down to electro-weak scale:
$\Rightarrow$ Weak-scale MSSM parameters
$\Rightarrow$ Masses and couplings



Current Status

- Standard Model experimentally very well confirmed

Current Status

- Standard Model experimentally very well confirmed
- Few experimental deviations
  - Dark matter

    $\sim 23\%$ Dark Matter content in the universe

    Possible candidate in the SM: Neutrinos

    $\leftrightarrow$ neutrino mass limits prevent accounting for total content
  - M_W

    $\sim 1\sigma$ deviation
  - LEP

    2.3σ excess in Higgs-like events near 98 GeV
  - $g - 2$ of the Muon

    3.4σ deviation

Current Status

- Standard Model experimentally very well confirmed
- Few experimental deviations
  - Dark matter

    $\sim 23\%$ Dark Matter content in the universe

    Possible candidate in the SM: Neutrinos

    $\leftrightarrow$ neutrino mass limits prevent accounting for total content
  - M_W

    $\sim 1\sigma$ deviation
  - LEP

    2.3σ excess in Higgs-like events near 98 GeV
  - $g-2$ of the Muon

    3.4σ deviation
- Some theoretical problems
  - No gauge coupling unification
  - Hierarchy problem

    (higher-order corrections to the Higgs-boson mass
    proportional to mass of the heaviest coupling particle
    $\rightarrow$ GUT scale (?))

Current Status

- Standard Model experimentally very well confirmed
- Few experimental deviations
  - Dark matter

    $\sim 23\%$ Dark Matter content in the universe

    Possible candidate in the SM: Neutrinos

    $\leftrightarrow$ neutrino mass limits prevent accounting for total content
  - M_W

    $\sim 1\sigma$ deviation
  - LEP

    2.3σ excess in Higgs-like events near 98 GeV
  - $g-2$ of the Muon

    3.4σ deviation
- Some theoretical problems
  - No gauge coupling unification
  - Hierarchy problem
    (higher-order corrections to the Higgs-boson mass
    proportional to mass of the heaviest coupling particle
    → GUT scale (?))
- Look for possible ultra-violet completions → Supersymmetry

Determining SUSY parameters

nowadays:

Parameters in the Lagrangian

m_0, μ, $\tan(\beta)$, $M_{\{1,2,3\}}$, …

Feynman diagrams,
RG evolution, …

Observables:

- Masses
- Kinematic endpoints
- Cross sections
- Branching ratios
- …

after SUSY discovery:

Observables

m_{h^0}, $\Delta m_{\tilde{g}\chi_1^0}$, three-particle edge($\chi_4^0$,$\tilde{e}_L$,$\chi_1^0$), BR, …

?

Lagrangian parameters

M_1	$\square \pm \square$ GeV
M_2	$\square \pm \square$ GeV
M_3	$\square \pm \square$ GeV
μ	$\square \pm \square$ GeV
$\tan\beta$	$\square \pm \square$
…	…

$\Rightarrow$ Tools to reconstruct SUSY parameters

Current Fits

$\longrightarrow$ Fits of current data to supersymmetry (only mSUGRA)

[Allanach, Cranmer, Lester, Weber 2005-7]

[Roszkowski, Ruiz de Austra, Trotta 2006/7]

[Buchmüller, Cavanaugh, De Roeck, Heinemeyer, Isidori, Paradisi, Ronga, Weber, Weiglein 2007]

Observables:

- Dark Matter $\Omega_{\mathrm{DM}} h^2$
- $g-2_\mu$
- M_W
- $\sin^2\theta_W$
- BR$(b \to s\gamma)$
- BR$(B_s \to \mu^+\mu^-)$
- $\ldots$

$\Rightarrow$ Predictions for SUSY mass spectrum

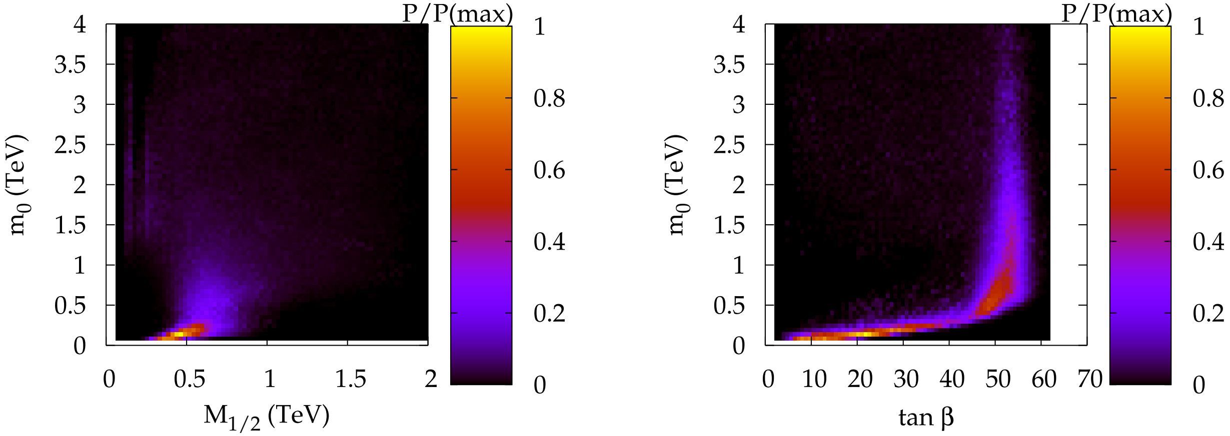
Current Fits (2)

Predictions for SUSY mass spectrum

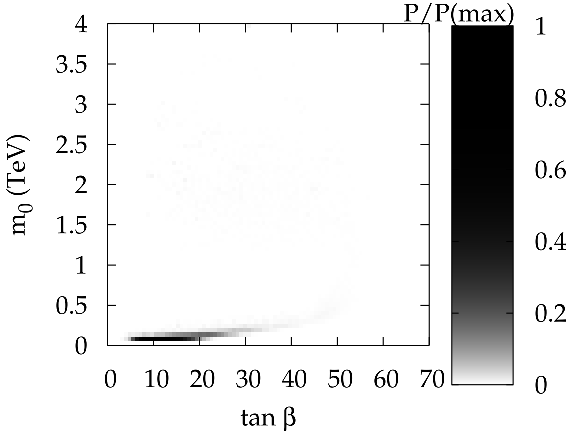
[plots by Allanach et al.]

Bayesian:

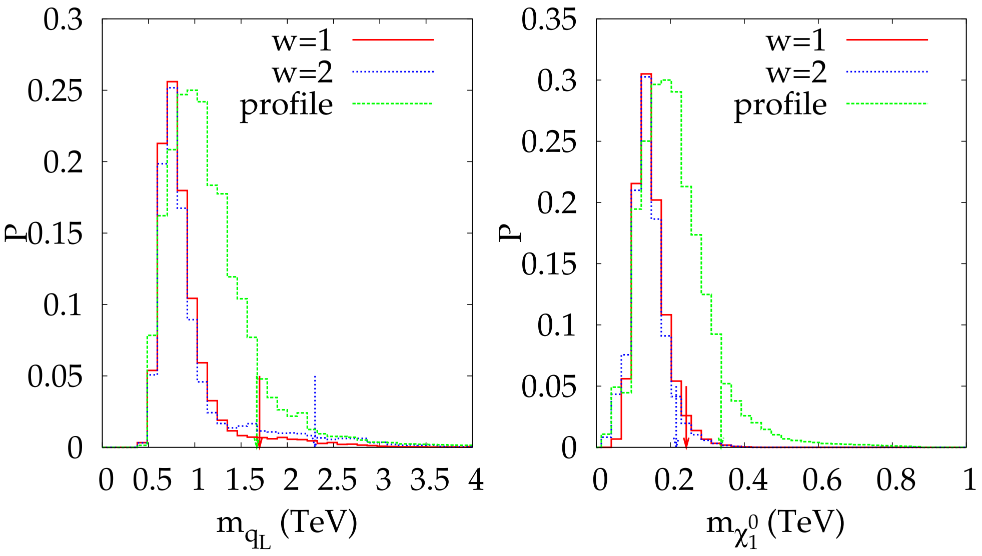
(flat $\tan\beta$ prior)

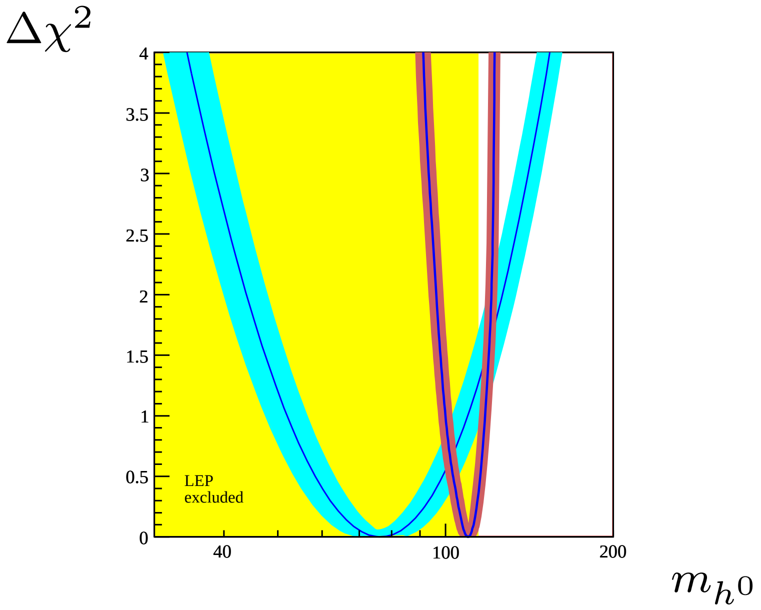


(REWSB+same order prior)



Current Fits (2)





[right-hand plot by Buchmüller et al.]

- Low-energy TeV-scale SUSY fits data very well
- ⇒ Mass ranges for SUSY particles
- Mass of the lightest Higgs boson compatible with LEP limit

Discovery of SUSY at the LHC
⇒ Additional observables from collider data
⇒ SFitter
(or Fittino)

[Bechtle, Desch, Wienemann]

What SFitter does

- Set of measurements
  - LHC measurements:
    kinematic edges, thresholds, masses, mass differences
    cross sections, branching ratios
  - ILC measurements
  - Indirect Constraints
    electro-weak: M_W, $\sin^2\theta_W$; $(g-2)_\mu$
    flavour: BR$(b \to s\gamma)$, BR$(B_s \to \mu^+\mu^-)$; dark matter: Ωh^2
  - or even ATLAS and CMS measurements separately
- Compare to theoretical predictions
  - Spectrum calculators: SoftSUSY, SuSPECT, ISASUSY [Allanach; Djouadi, Kneur, Moultaka; Baer, Paige, Protopopescu, Tata]
  - LHC cross sections: Prospino2 [Plehn et al.]
  - LC cross sections: MsmLib [Ganis]
  - Branching Ratios: SUSYHit (HDecay + SDecay) [Djouadi, Mühlleitner, Spira]
  - micrOMEGAs [Bélanger, Boudjema, Pukhov, Semenov]
  - g-2 [Alexander, Stöckinger]
- Using as glue: SLHAio [Kreiß]

Parameter Scans

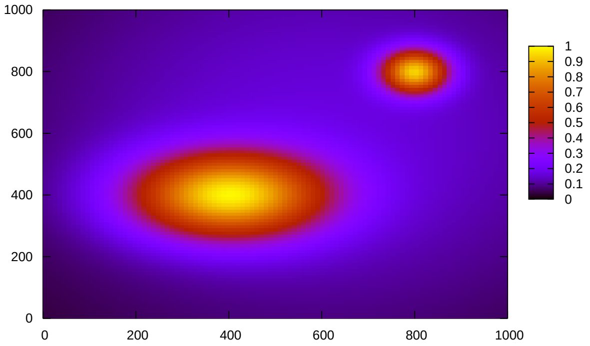
- MSSM parameter space is high-dimensional:
  - SM: 3+ parameters (m_t, α_s, α, $\ldots$)
  - mSUGRA: 5 parameters (m_0,$m_{1/2}, A_0, \tan(\beta), \mathrm{sgn}(\mu)$)
  - General MSSM: 105 parameters
- On loop-level observables depend on every parameter
  Simple inversion of the relations not possible
  $\Rightarrow$ Parameter scans
- Error estimates on parameters in the minimum

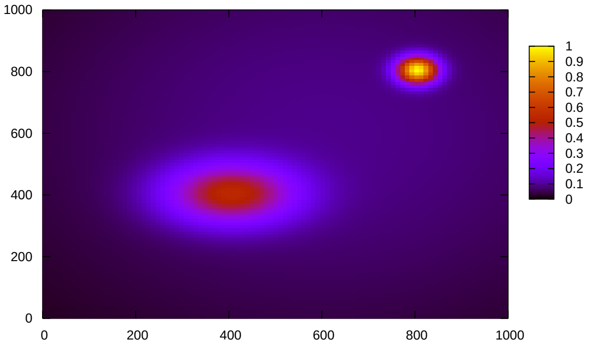
Parameter Scans

- MSSM parameter space is high-dimensional:
  - SM: 3+ parameters (m_t, α_s, α, $\ldots$)
  - mSUGRA: 5 parameters (m_0,$m_{1/2}, A_0, \tan(\beta), \mathrm{sgn}(\mu)$)
  - General MSSM: 105 parameters
- On loop-level observables depend on every parameter
  Simple inversion of the relations not possible
  $\Rightarrow$ Parameter scans
- Error estimates on parameters in the minimum

Find best points (best χ^2) using different fitting techniques:

- Gradient search (Minuit) $\left(\begin{array}{r} + \text{ Reasonably fast} \\ - \text{ Limited convergence, only best fit} \end{array}\right)$





Parameter Scans

- MSSM parameter space is high-dimensional:
  - SM: 3+ parameters (m_t, α_s, α, $\ldots$)
  - mSUGRA: 5 parameters (m_0,$m_{1/2}$, $A_0, \tan(\beta), \mathrm{sgn}(\mu)$)
  - General MSSM: 105 parameters
- On loop-level observables depend on every parameter
  Simple inversion of the relations not possible
  $\Rightarrow$ Parameter scans
- Error estimates on parameters in the minimum

Find best points (best χ^2) using different fitting techniques:

- Gradient search (Minuit) $\left(\begin{array}{c} + \text{ Reasonably fast} \\ - \text{ Limited convergence, only best fit} \end{array} \right)$
- fixed Grid scan $\left(\begin{array}{c} + \text{ scans complete parameter space} \\ - \text{ many points needed } (\mathcal{O}(e^N)) \end{array} \right)$

Parameter Scans

- MSSM parameter space is high-dimensional:
  - SM: 3+ parameters (m_t, α_s, α, $\ldots$)
  - mSUGRA: 5 parameters (m_0,$m_{1/2}, A_0, \tan(\beta), \mathrm{sgn}(\mu)$)
  - General MSSM: 105 parameters
- On loop-level observables depend on every parameter
  Simple inversion of the relations not possible
  $\Rightarrow$ Parameter scans
- Error estimates on parameters in the minimum

Find best points (best χ^2) using different fitting techniques:

- Gradient search (Minuit) $\left(\begin{array}{c} + \text{ Reasonably fast} \\ - \text{ Limited convergence, only best fit} \end{array}\right)$
- fixed Grid scan $\left(\begin{array}{c} + \text{ scans complete parameter space} \\ - \text{ many points needed (}\mathcal{O}(e^N)\text{)} \end{array}\right)$
- Weighted Markov Chains

Markov Chains

Markov Chain (MC):

- Sequence of points, chosen by an algorithm (Metropolis-Hastings), only depending on its direct predecessor
- Picks a set of ”average” points according to a potential V (e.g. inverse log-likelihood, $1/\chi^2$)
- Point density resembles the value of V (i.e. more points in region with high V)
- Scans high dimensional parameter spaces efficiently [Baltz, Gondolo 2004]
- mSUGRA MC scans with current exp. limits

[Allanach, Cranmer, Lester, Weber 2005-7; Roszkowski, Ruiz de Austra, Trotta 2006/7]

Weighted Markov Chains

Weighted Markov Chains:

Improved evaluation algorithm for binning: [Plehn, MR]

- Weight points with value of V:
- Take care of
  - Overcounting because point density is already weighted ($\frac{\text{number of points}}{\sum_{\text{points}} 1/V(\text{point})}$)
    [based on Ferrenberg, Swendsen 1988]
  - Correct account for regions with zero probability
    (maintain additional chain which stores points rejected because $V(\text{point}) = 0$)

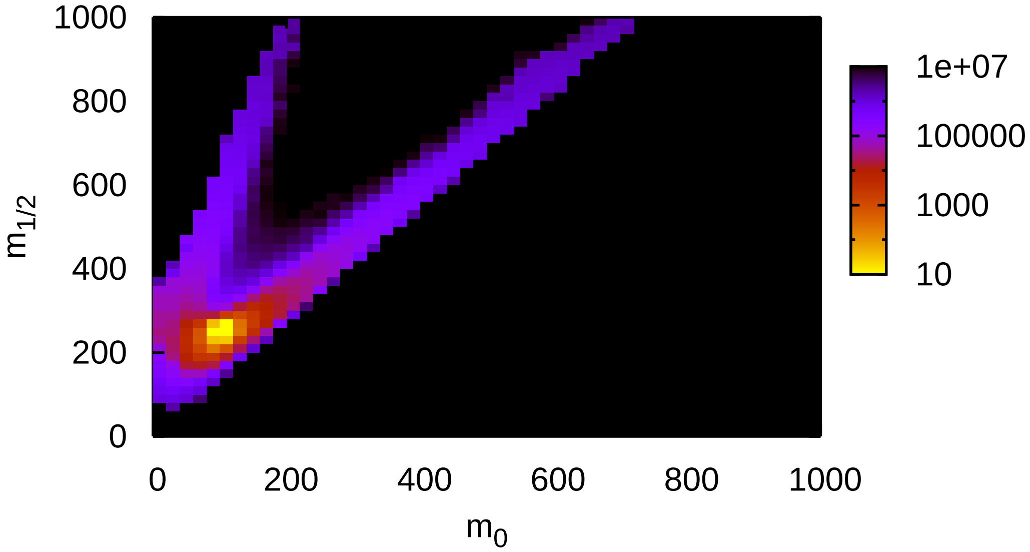
$+$ Fast scans of high-dimensional spaces $\mathcal{O}(N)$
$+$ Does not rely on shape of χ^2 (no derivatives used)
$+$ Can find secondary distinct solutions
$-$ Exact minimum difficult to find $\Rightarrow$ Additional gradient fit
$-$ Bad choice of proposal function for next point leads to bad coverage of the space

mSUGRA as a Toy Model

mSUGRA with LHC measurements (SPS1a kinematic edges):
pick one set of ”measurements”, randomly smeared from the true values

Free parameters:
m_0, $m_{1/2}$, $\tan(\beta)$, A_0, $\mathrm{sgn}(\mu)$, m_t

SFitter output 1:
Fully-dimensional exclusive likelihood map
(colour:
minimum χ^2 over all unseen parameters)



SFitter output 2:
Ranked list of minima:

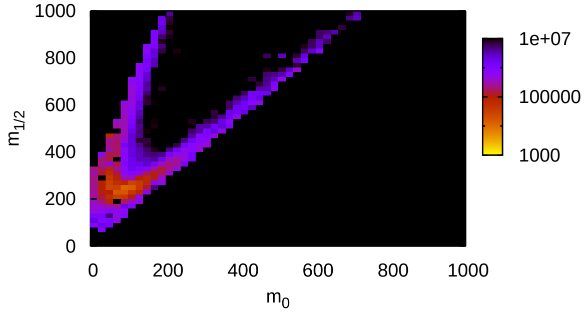
	χ^2	m_0	$m_{1/2}$	$\tan(\beta)$	A_0	μ	m_t
SPS1a		100.0	250.0	10.0	-100.0	$+$	171.4
1)	1.32	100.4	251.2	12.7	-71.7	$+$	171.9
2)	7.18	106.3	243.6	14.3	-103.3	$-$	170.7
3)	13.9	103.5	258.2	12.2	848.4	$+$	174.4
4)	75.1	107.3	251.4	15.1	778.8	$-$	173.6

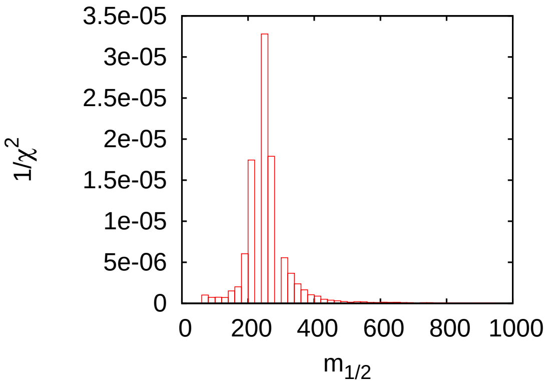
Bayesian or Frequentist?

SFitter provides full-dimensional log-likelihood map

→ ”project” onto plotable 1- or 2-dimensional spaces

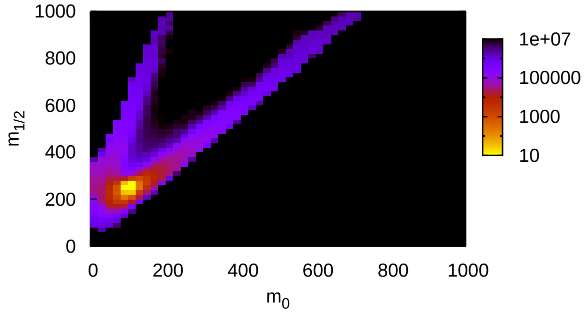
Bayesian:

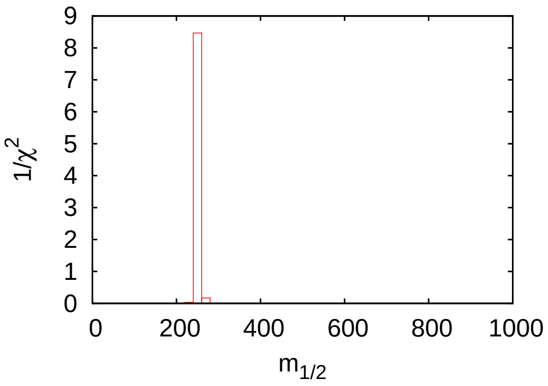




Marginalisation of χ^2 in all other directions

Frequentist:





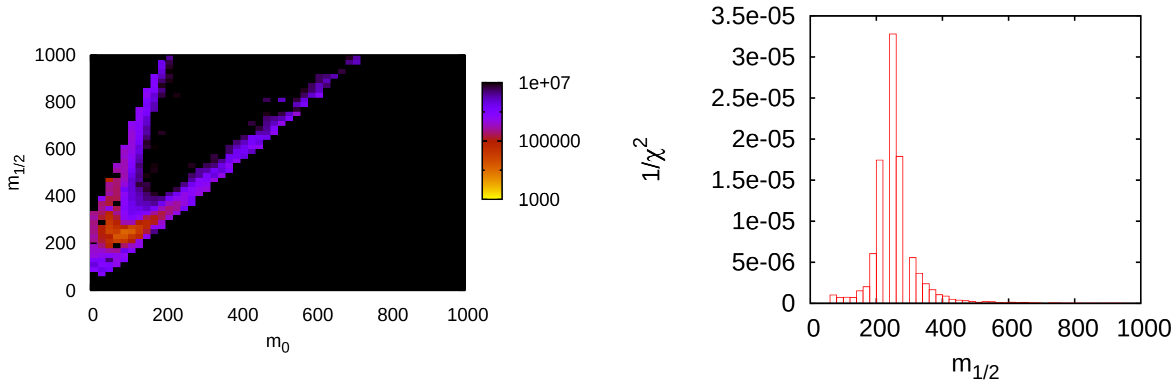
Profile likelihood: Value of bin is value of smallest χ^2 occuring in this bin

Bayesian or Frequentist?

SFitter provides full-dimensional log-likelihood map

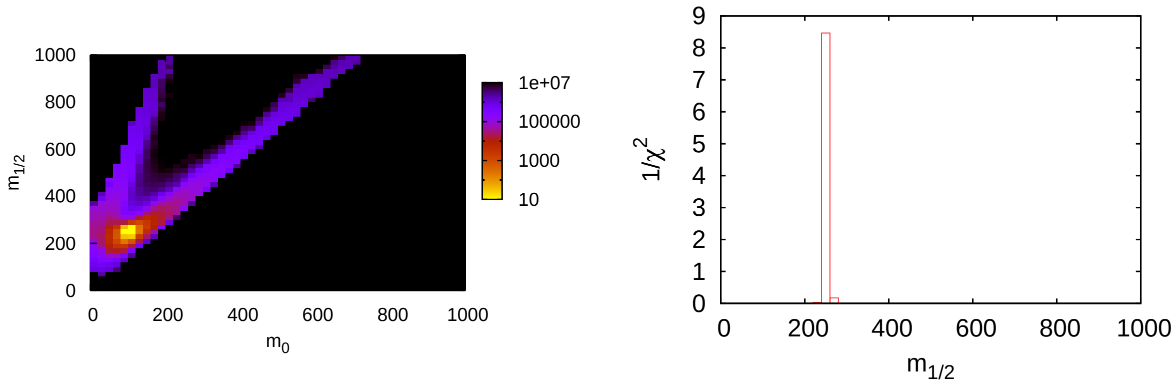
$\longrightarrow$ ”project” onto plotable 1- or 2-dimensional spaces

Bayesian:



Marginalisation of χ^2 in all other directions

Frequentist:



Profile likelihood: Value of bin is value of smallest χ^2 occuring in this bin

Different methods answer different questions.

$\Rightarrow$ Bayesian and Frequentist!

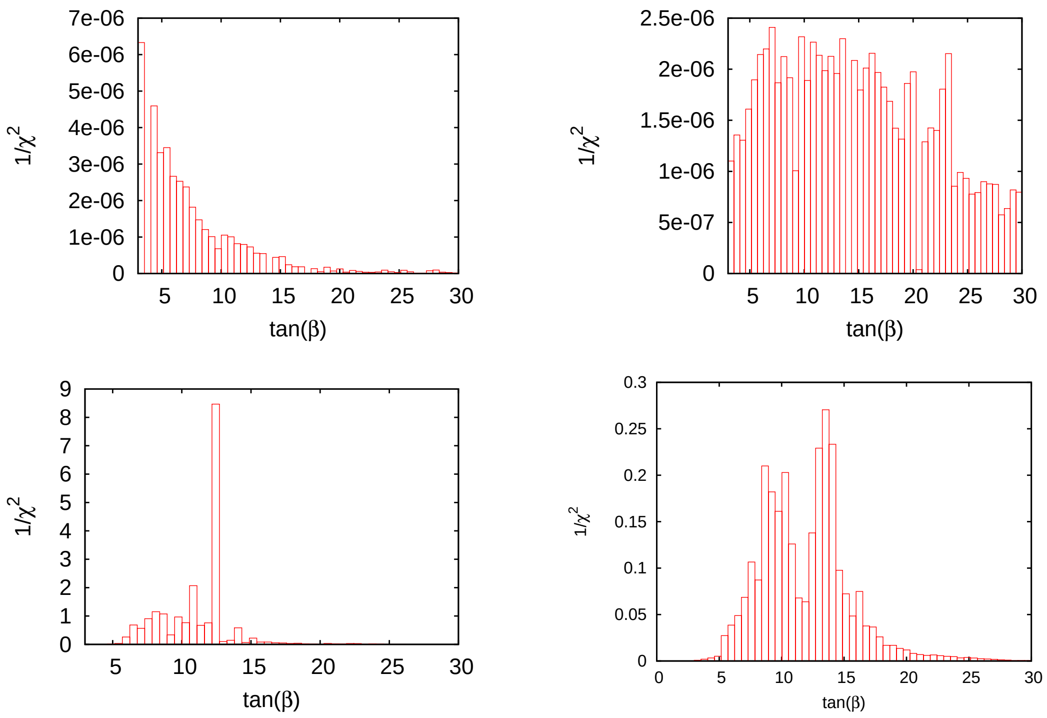
Everybody can choose his/her favourite analysis . . .

Purely high-scale model

m_0, $m_{1/2}$, A_0 defined at the GUT-scale $\Leftrightarrow$ $\tan(\beta)$ defined at the weak scale
$\Rightarrow$ Replace $\tan(\beta)$ with high-scale quantity B
$\Rightarrow$ Flat prior in B yields prior $\propto \frac{1}{\tan(\beta)^2}$

SPS1a with LHC kinematic edges ($\tan(\beta)$ vs. $1/\chi^2$):

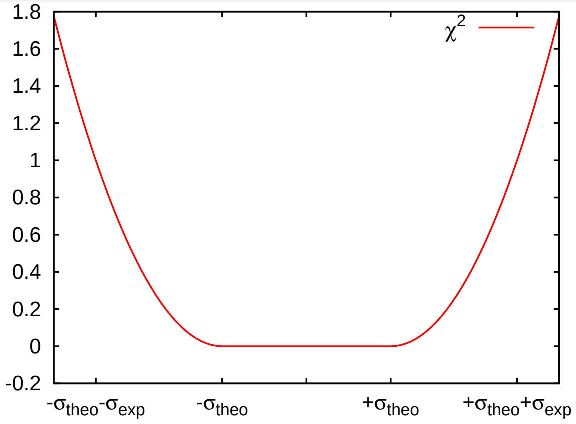
flat B prior | flat $\tan(\beta)$ prior



Bayesian:
Large influence of choice of prior
Choosing flat B prior strongly favours low values of $\tan(\beta)$.

Frequentist:
Two plots should be identical (no prior in χ^2 calculation)
Indirect influence via Markov Chain proposal function

Error determination



Treatment of errors:

- All experimental errors are Gaussian
  $$\sigma^2_{\text{exp}} = \sigma^2_{\text{stat}} + \sigma^2_{\text{syst}(j)} + \sigma^2_{\text{syst}(l)}$$
- Systematic errors from jet ($\sigma_{\text{syst}(j)}$) and lepton energy scale ($\sigma_{\text{syst}(l)}$) assumed 99% correlated each
- Theory error added as box-shaped (RFit scheme [Hoecker, Lacker, Laplace, Lediberder])

$$\Rightarrow -2\log L \equiv \chi^2 = \sum_{\text{measurements}} \begin{cases} 0 & \text{for } |x_{\text{data}} - x_{\text{pred}}| < \sigma_{\text{theo}} \\ \left(\frac{|x_{\text{data}} - x_{\text{pred}}| - \sigma_{\text{theo}}}{\sigma_{\text{exp}}}\right)^2 & \text{for } |x_{\text{data}} - x_{\text{pred}}| \geq \sigma_{\text{theo}} \end{cases}$$

$\Rightarrow$ Parameter errors:

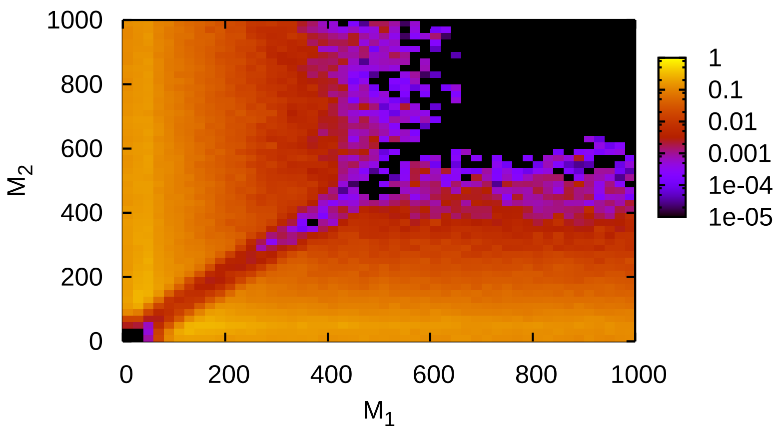
	SPS1a	$\Delta^{\text{theo}-\text{exp}}_{\text{zero}}$	$\Delta^{\text{theo}-\text{exp}}_{\text{zero}}$	$\Delta^{\text{theo}-\text{exp}}_{\text{gauss}}$	$\Delta^{\text{theo}-\text{exp}}_{\text{flat}}$
		LHC masses	LHC edges		
m_0	100	4.10	0.50	2.97	2.17
$m_{1/2}$	250	2.01	0.73	2.99	2.64
$\tan\beta$	10	1.42	0.65	3.36	2.45
A_0	-100	35.4	21.2	51.5	49.6
m_t	171.4	0.93	0.26	0.89	0.97

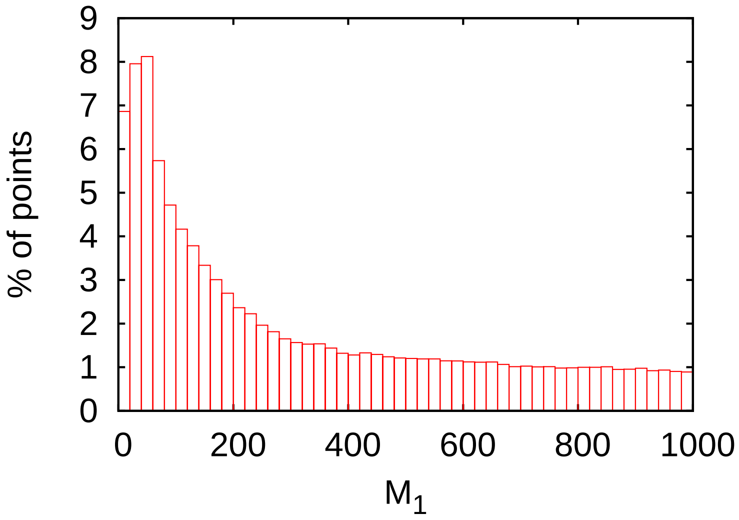
$\Rightarrow$ Use kinematic edges for parameter determination instead of masses

Weak-scale MSSM

- No need to assume specific SUSY-breaking scenario
  ⇒ SUSY-breaking mechanism should be induced from data
- Use of Markov Chains makes scanning the 19-dimensional parameter space feasible
- Lack of sensitivity on one parameter does not slow down the scan
  (no need to fix parameters)
- Same SFitter output as before: Minima list and Likelihood map

MSSM using SPS1a spectrum and LHC kinematic edges:
(Bayesian, full parameter space)



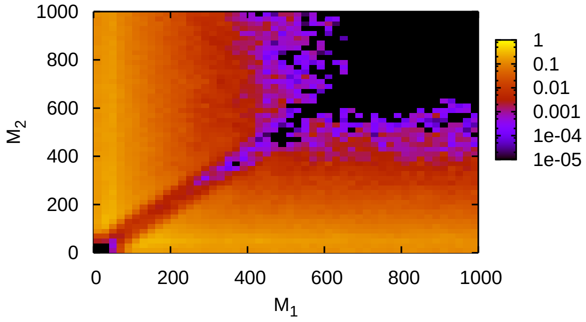


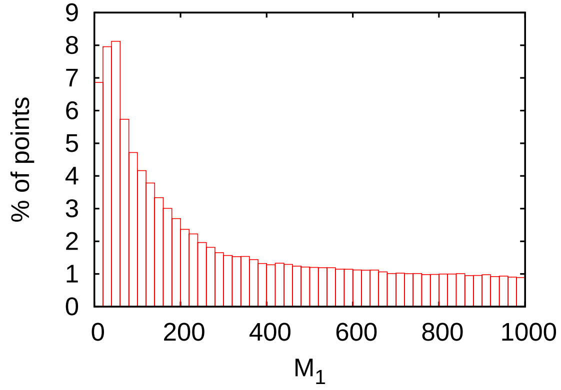
Search Strategy (1)

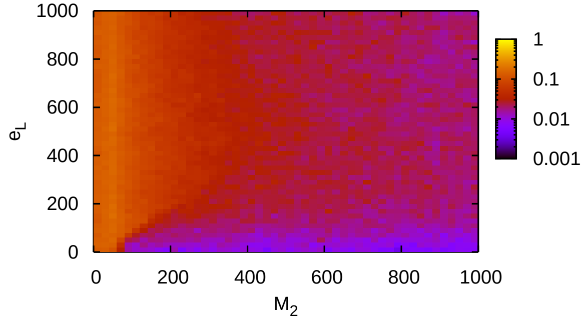
Full scan of 19D parameter space challenging

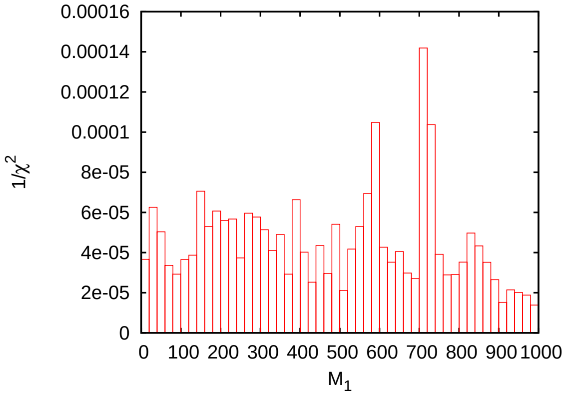
Four-step procedure yields better and faster results:

- Weighted-Markov-Chain run with flat pdf over full parameter space
  5 best points additionally minimised
  (full scan, no bias on starting point)









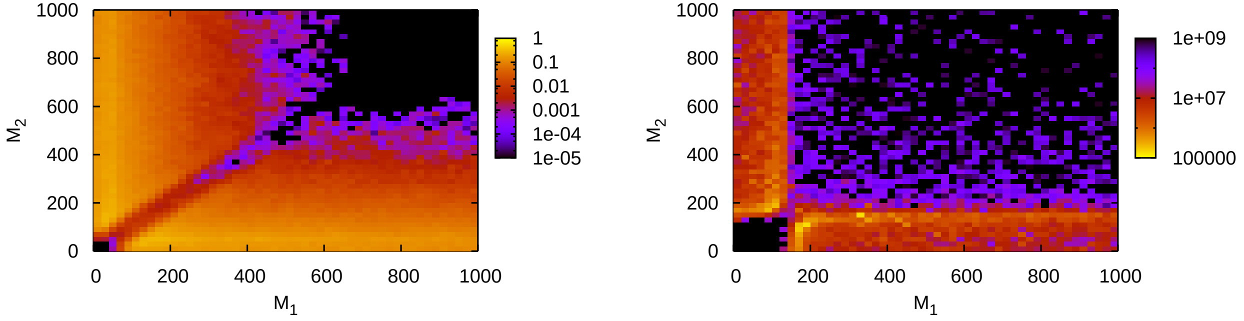
Correlations not aligned with parameters ⇒ washed out in plots

Search Strategy (2)

Full scan of 19D parameter space challenging
Four-step procedure yields better and faster results:

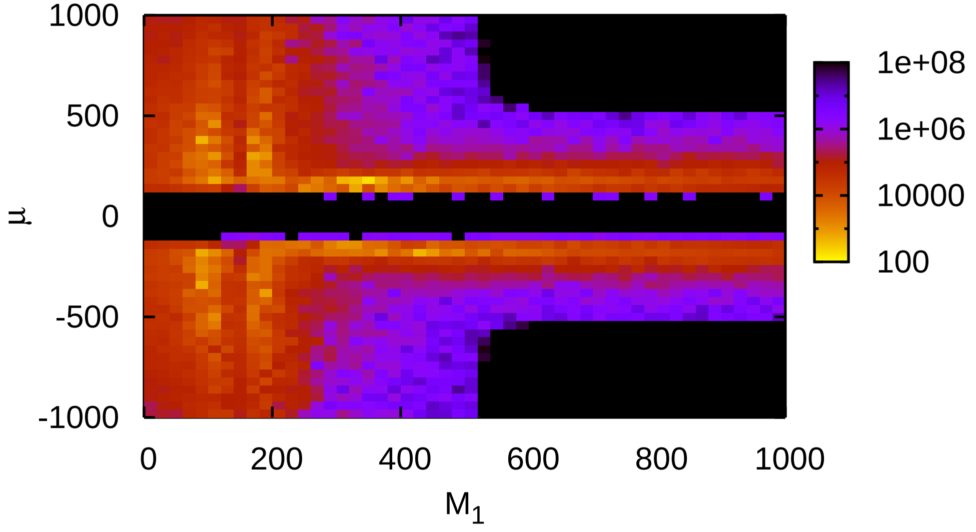
- Weighted-Markov-Chain run with flat pdf over full parameter space
  5 best points additionally minimised
  (full scan, no bias on starting point)
- Weighted-Markov Chain with flat pdf on Gaugino-Higgsino subspace:
  $M_1, M_2, M_3, \mu, \tan\beta, m_t$
  Additional Minuit run with 15 best solutions

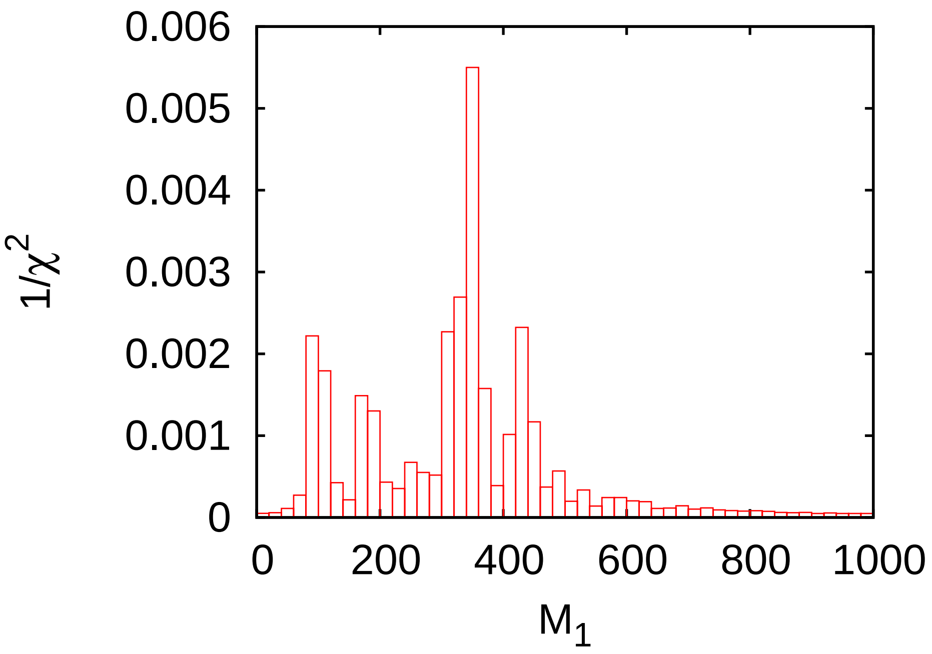
Step 1 Step 2



Search Strategy (2) - results

- Only three neutralinos (χ_1^0, χ_2^0, χ_4^0) with masses (97.2 GeV , 180.5 GeV , 375.6 GeV) and no charginos observable at the LHC in SPS1a
- $\Rightarrow$ Mapping (M_1, M_2, μ) $\rightarrow$ (χ_1^0, χ_2^0, χ_4^0) not unique
- $\mathrm{sgn}\,\mu$ basically undetermined by collider data
- $\Rightarrow$ 8-fold solution





Search Strategy (2) - results

- Only three neutralinos (χ_1^0, χ_2^0, χ_4^0) with masses (97.2 GeV , 180.5 GeV , 375.6 GeV) and no charginos observable at the LHC in SPS1a
- $\Rightarrow$ Mapping (M_1, M_2, μ) $\rightarrow$ (χ_1^0, χ_2^0, χ_4^0) not unique
- $\operatorname{sgn}\mu$ basically undetermined by collider data
- $\Rightarrow$ 8-fold solution

Degenerate Solutions

- In total 19 parameters constrained by 22 measurements
- Measurements constructed from only 15 underlying masses
- ⇒ Complete determination of parameter set not possible
- Five parameters not well constrained
    - m_A
      ← no heavy Higgses measurable
    - $M_{\tilde{t}_R}$
    - A_t
      ← stop sector parameters do not enter edge measurements
    - $M_{\tilde{\tau}_L}$ or $M_{\tilde{\tau}_R}$
      ← only the lighter stau measured
    - $\tan\beta$
      ← change can always be accomodated by rotating M_1, M_2, $M_{\tilde{q}_3}$, …
- Single common link: m_{h^0}
- ⇒ 4-dimensional hyperplane in parameter space undetermined
- Can still assign errors to some of the badly determined parameters

Error analysis

- Technical procedure as in mSUGRA case:
  - 10000 smeared data sets
  - Minimum determined for each data set individually
  - Error determined from fit with Gaussian
- Most constrained parameters determinable with $\sim 5\%$ accuracy
- Inclusion of theory errors leads to an increase of factor 2 on the parameter errors
- ILC data complementary to LHC
- Combination of the two experiments allows for precise determination of all parameters

	LHC	ILC	LHC+ILC	SPS1a
M_1	102.1± 7.8	103.0± 1.1	103.1±0.84	103.1

m_A	406.3±$\mathcal{O}(10^3)$	393.8± 1.6	393.9± 1.6	394.9
$M_{\tilde{t}_R}$	415.8±$\mathcal{O}(10^2)$	440.0±$\mathcal{O}(4 \cdot 10^2)$	410.7±48.4	408.3

Testing Unification

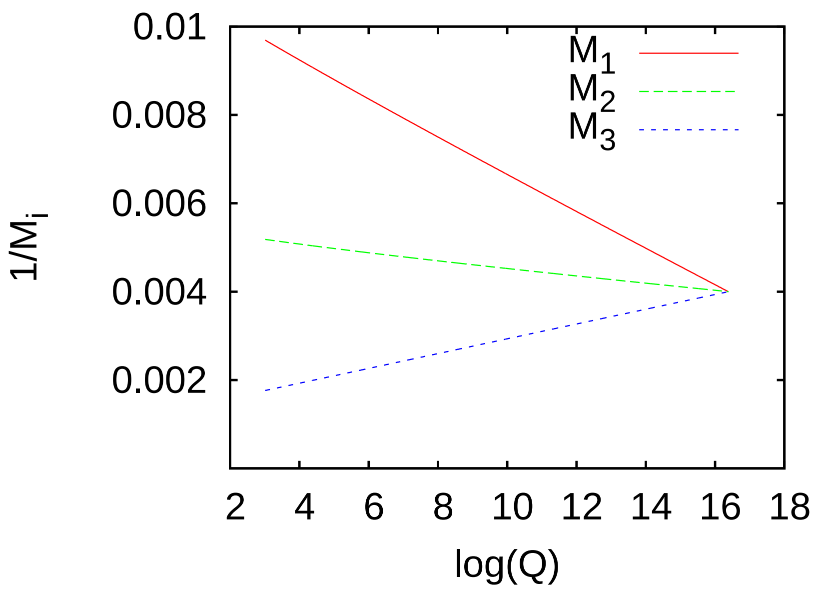
Apparent unification of gauge coupling parameters in the MSSM

Question arises: Do other parameters unify as well?

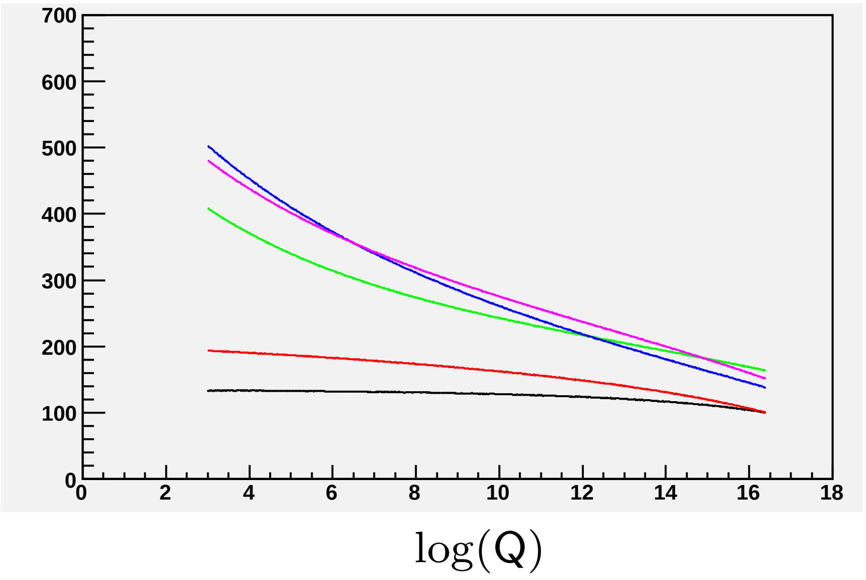
⇒ Should be tested by bottom-up running from weak scale to Planck scale

⇒ Can give hints about supersymmetry breaking
(e.g. test scalar-mass sum rules with a sliding scale) [Schmaltz et al.]

Bottom-up running of gaugino masses and 3rd-generation sfermion masses:



$M_{\tilde\tau_R}, M_{\tilde\tau_L}, M_{\tilde t_R}, M_{\tilde b_R}, M_{\tilde q3_L}$; $\Delta M_3 = -10$ GeV



Testing Unification

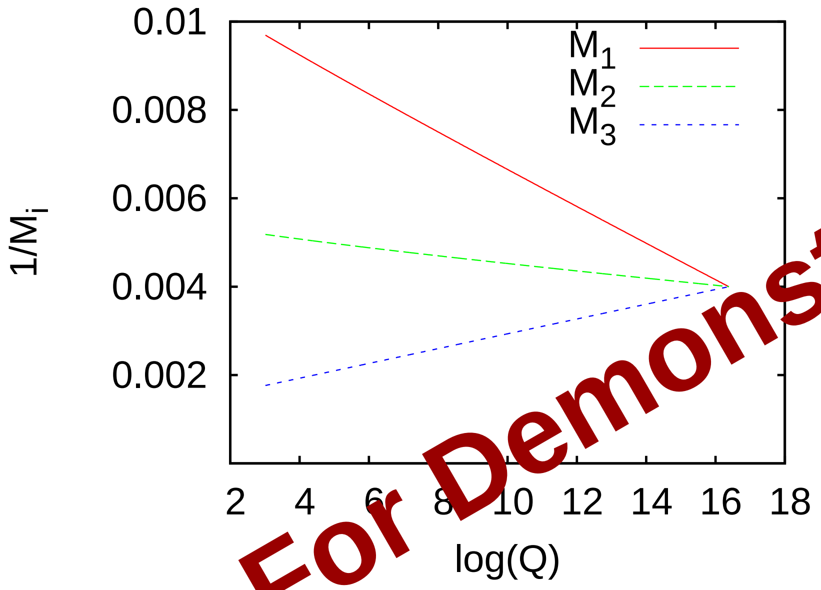
Apparent unification of gauge coupling parameters in the MSSM

Question arises: Do other parameters unify as well?

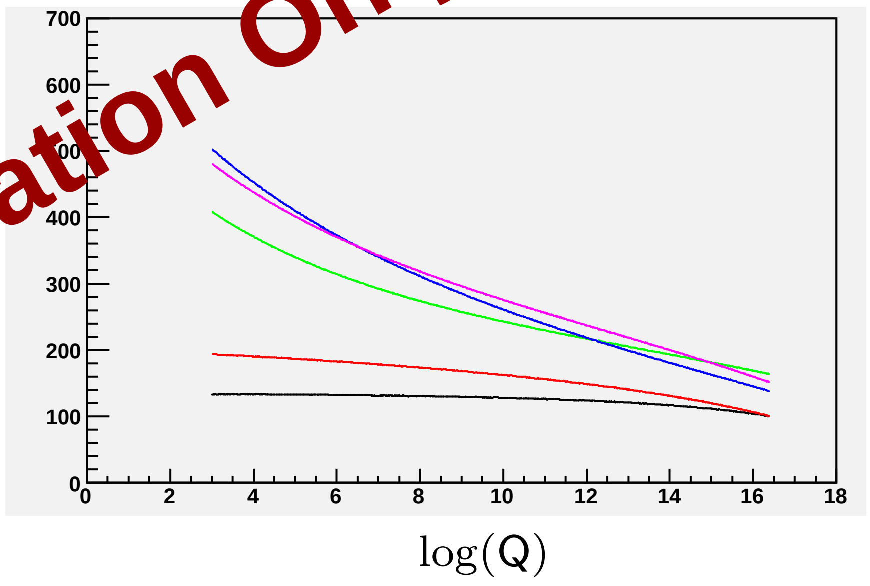
⇒ Should be tested by bottom-up running from weak scale to Planck scale

⇒ Can give hints about supersymmetry breaking
(e.g. test scalar-mass sum rules with a sliding scale) [Schmaltz et al.]

Bottom-up running of gaugino masses and 3rd-generation sfermion masses:



$M_{\tilde\tau_R}, M_{\tilde\tau_L}, M_{\tilde t_R}, M_{\tilde b_R}, M_{\tilde q3_L}$; $\Delta M_3 = -10$ GeV



Summary & Outlook

- Current status: Low-energy supersymmetry fits precision data very well
- Parameter scans important to determine Lagrangian parameters from observables
- Problem of high-dimensional parameter spaces
- Markov Chains can do this effectively
- Improved algorithm developed
- Two types of output: Likelihood map and list of best points
- Both Bayesian and Frequentist from likelihood map
- Bayesian output significantly dependent on priors
- Tested with mSUGRA SPS1a:
  can reconstruct SPS1a from (simulated) LHC data
- Repeated procedure with weak-scale MSSM:
  reconstruction works as well
- SFitter (despite its name) not tied to SUSY
  $\longrightarrow$ extend to other models/problems

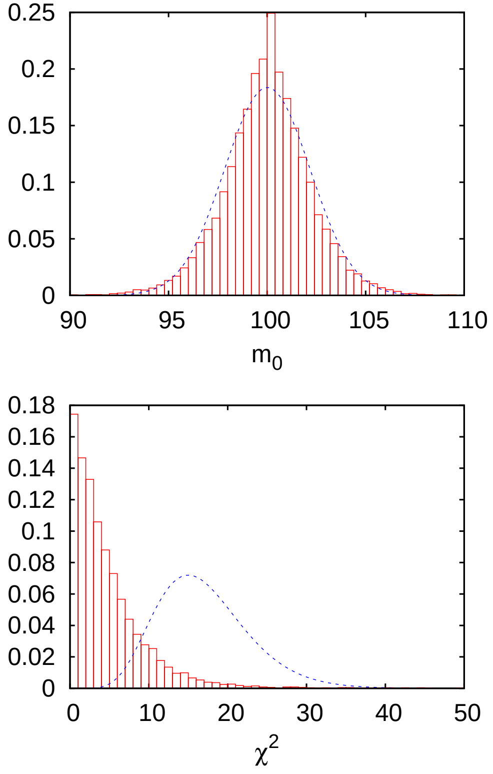
Error determination

Minuit output not usable for flat theory errors:

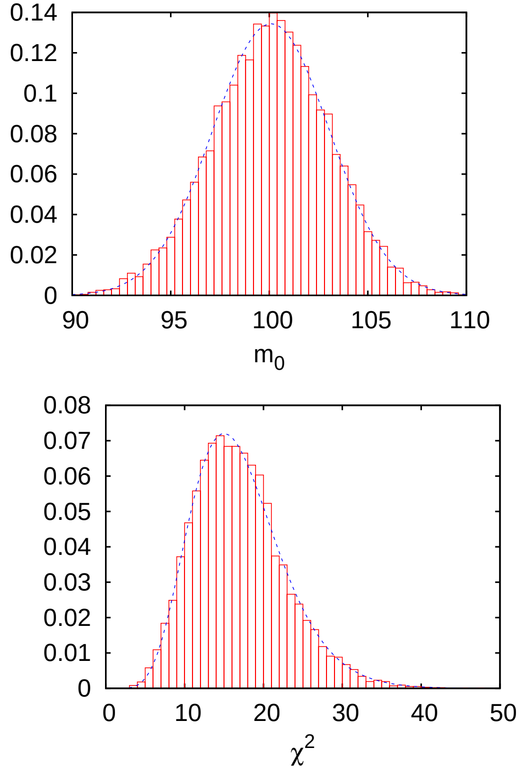
- Migrad function depends on parabolic approximation
- Cannot determine $\Delta\chi^2$ for Minos to yield 68% CL intervals

$\Rightarrow$ Need more general approach

- Perform $10,000$ toy experiments with measurements smeared around correct value
- Minimise each toy experiment
- Plot resulting distribution of parameter points and fit with Gaussian



Flat theory errors



Gaussian theory errors

MSSM errors

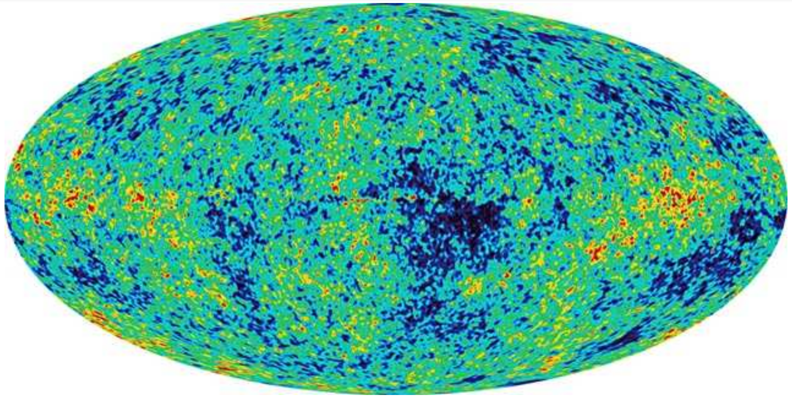
Dark Matter



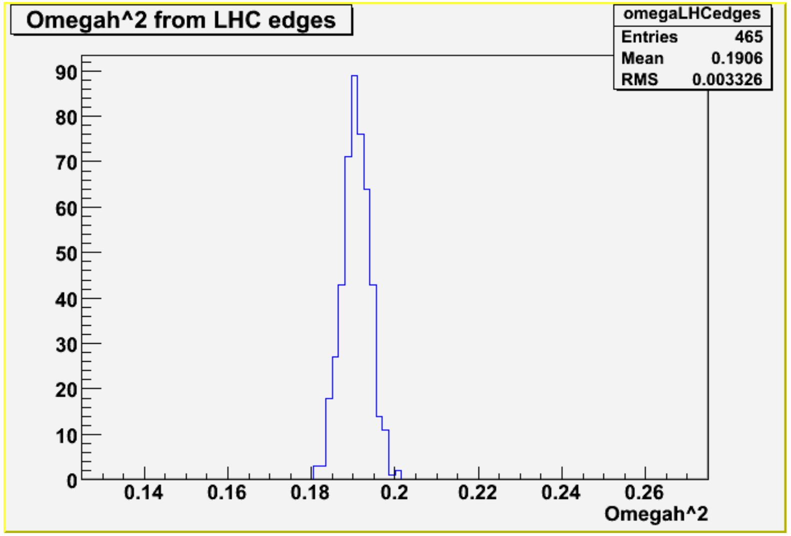
[NASA/WMAP Science Team]

Content of the universe:

- 73% Dark energy
- 4% Ordinary matter
- 23% Dark matter

MSSM: χ_1^0 as LSP ideal candidate for cold dark matter (CDM): massive, weakly interacting

- SFitter: Determine Lagrangian parameters ⇒ Spectrum and couplings
- e.g. micrOMEGAs: Calculate relic density $\Omega_{\text{CDM}} h^2 = n_{\text{LSP}} m_{\text{LSP}}$ [Bélanger et al.]
- $\Rightarrow$ Prediction of $\Omega_{\text{CDM}} h^2$
  LHC : $\Omega_{\text{CDM}} h^2 = 0.1906 \pm 0.0033$
  LHC+ILC: $\Omega_{\text{CDM}} h^2 = 0.1910 \pm 0.0003$
  (improvement by one order of magnitude)



- Compare with experiment
  (Measurement of the fluctuations of the
  cosmic microwave background):

WMAP: $\Omega_{\text{CDM}} h^2 = 0.1277 \pm 0.008$ [astro-ph/0603449]
Planck: $\Omega_{\text{CDM}} h^2 = \quad ? \pm 0.0016$

Example

Test function (5-dim):

- Small Hypersphere $r = 100$, $V_{\text{max}} = 75$ @ $(650, 250, 350, 350, 350)$
- Cuboid $d = (173, 120, 200, 200, 200)$, $V_{\text{max}} = 60$ @ $(850, 225, 650, 650, 650)$
- Cube $d = (100, 100, 300, 300, 300)$, $V_{\text{max}} = 25$ @ $(750, 750, 450, 450, 450)$
- Gaussian $\sigma = (50, 150, 150, 150, 150)$, $V_{\text{max}} = 16$ @ $(250, 250, 550, 550, 550)$
- Big Hypersphere $r = 300$, $V_{\text{max}} = 12$ @ $(350, 650, 650, 650, 650)$
- Background $V = 0.1 + 4 \cdot 10^{-30} \cdot x_1^2 x_2^2 x_3^2 x_4^2 x_5^2$

Plot Details

- Parameters: $x_1, \ldots, x_5 \in [0, 1000]$
- Bins: 50×50
- PDF: Breit-Wigner ($\frac{1}{1+\Delta x_i^2/\sigma^2}$) with $\sigma = 100$
- Number of Markov chains: 9
- Number of points per chain: 10^7
- Number of function evaluations: $33, 797, 153$
- Acceptance ratio: 0.19
- Final r (measure of convergence): 1.815
- CPU time (3 GHz): 150 min
