# Outline

- Supersymmetry
- Current Status
- Determining SUSY Parameters
- Kinematic Edges as Experimental Input
- Possible Collider Results
- Dark Matter

# Supersymmetry

Symmetry between bosons and fermions:

$$Q |\text{boson}\rangle = |\text{fermion}\rangle;$$

$$Q |\text{fermion}\rangle = |\text{boson}\rangle$$

$Q$ : Supersymmetry Operator

Simplest model:

Minimal Supersymmetric Standard Model (MSSM)

- Supersymmetric partner to each Standard Model particle
- Two Higgs doublets  $\Rightarrow$  5 Higgs bosons ( $h^0, H^0, A^0, H^\pm$ )
- Particles with same quantum numbers mix  
(e.g. Zino, Photino, 2 Higgsino  $\rightarrow$  4 Neutralino)

Unification at the GUT scale ( $\sim 10^{16}$  GeV):

- Apparent unification of gauge couplings (general feature of MSSM)
- Common scalar mass:  $m_0$
- Common sfermion mass:  $m_{1/2}$
- Common trilinear coupling:  $A_0$

plus

- ratio of the Higgs vacuum expectation values at the electro-weak scale:  $\tan \beta = \frac{v_2}{v_1}$
- one sign:  $\text{sgn } \mu$

Evolve three parameters defined at the GUT scale via renormalisation group equations down to electro-weak scale:

- ⇒ Weak-scale MSSM parameters
- ⇒ Masses and couplings

# Current Status

- Standard Model experimentally very well confirmed

# Current Status

- Standard Model experimentally very well confirmed
- Few experimental deviations
  - Dark matter
    - ~ 23% Dark Matter content in the universe
    - Possible candidate in the SM: Neutrinos
    - ↔ neutrino mass limits prevent accounting for total content
  - $M_W$ 
    - ~  $1\sigma$  deviation
  - LEP
    - 2.3 $\sigma$  excess in Higgs-like events near 98 GeV
  - $g - 2$  of the Muon
    - 3.4 $\sigma$  deviation

# Current Status

- Standard Model experimentally very well confirmed
- Few experimental deviations
  - Dark matter
    - ~ 23% Dark Matter content in the universe
    - Possible candidate in the SM: Neutrinos
    - ↔ neutrino mass limits prevent accounting for total content
  - $M_W$ 
    - ~  $1\sigma$  deviation
  - LEP
    - 2.3 $\sigma$  excess in Higgs-like events near 98 GeV
  - $g - 2$  of the Muon
    - 3.4 $\sigma$  deviation
- Some theoretical problems
  - No gauge coupling unification
  - Hierarchy problem
    - (higher-order corrections to the Higgs-boson mass proportional to mass of the heaviest coupling particle
    - GUT scale (?))

# Current Status

- Standard Model experimentally very well confirmed
- Few experimental deviations
  - Dark matter
    - ~ 23% Dark Matter content in the universe
    - Possible candidate in the SM: Neutrinos
    - ↔ neutrino mass limits prevent accounting for total content
  - $M_W$ 
    - ~  $1\sigma$  deviation
  - LEP
    - 2.3 $\sigma$  excess in Higgs-like events near 98 GeV
  - $g - 2$  of the Muon
    - 3.4 $\sigma$  deviation
- Some theoretical problems
  - No gauge coupling unification
  - Hierarchy problem
    - (higher-order corrections to the Higgs-boson mass proportional to mass of the heaviest coupling particle
    - GUT scale (?))
- Look for possible ultra-violet completions → Supersymmetry

# Determining SUSY parameters

nowadays:

## Parameters in the Lagrangian

$m_0, \mu, \tan(\beta), M_{\{1,2,3\}}, \dots$

Feynman diagrams,  
RG evolution, ...

Observables:

- Masses
- Kinematic endpoints
- Cross sections
- Branching ratios
- ...

after SUSY discovery:

## Observables

$m_{h^0}, \Delta m_{\tilde{g}\chi_1^0}, \text{three-particle edge}(\chi_4^0, \tilde{e}_L, \chi_1^0), \text{BR}, \dots$

?

Lagrangian parameters

$M_1$	<input type="text"/> $\pm$ <input type="text"/> GeV
$M_2$	<input type="text"/> $\pm$ <input type="text"/> GeV
$M_3$	<input type="text"/> $\pm$ <input type="text"/> GeV
$\mu$	<input type="text"/> $\pm$ <input type="text"/> GeV
$\tan \beta$	<input type="text"/> $\pm$ <input type="text"/>
...	...

⇒ Tools to reconstruct SUSY parameters

# Current Fits

→ Fits of current data to supersymmetry (only mSUGRA)

[Allanach, Cranmer, Lester, Weber 2005-8]

[Roszkowski, Ruiz de Austra, Trotta 2006-8]

[Buchmüller, Cavanaugh, De Roeck, Heinemeyer, Isidori, Olive, Paradisi, Ronga, Weber, Weiglein 2007/8]

Observables:

- Dark Matter  $\Omega_{\text{DM}} h^2$
- $g - 2_\mu$
- $M_W$
- $\sin^2 \theta_W$
- $\text{BR}(b \rightarrow s\gamma)$
- $\text{BR}(B_s \rightarrow \mu^+ \mu^-)$
- ...

⇒ Predictions for SUSY mass spectrum

# Current Fits (2)

Predictions for SUSY mass spectrum

[plots by Allanach et al.]

Bayesian:

(flat  $\tan \beta$  prior)

(REWSB+same order prior)

# Current Fits (2)

[right-hand plot by Buchmüller et al.]

- Low-energy TeV-scale SUSY fits data very well
- $\Rightarrow$  Mass ranges for SUSY particles
- Mass of the lightest Higgs boson compatible with LEP limit

## Discovery of SUSY at the LHC

$\Rightarrow$  Additional observables from collider data

$\Rightarrow$  SFitter

(or Fittino)

(or GFitter)

[Lafaye, Plehn, MR, Zerwas]

[Bechtle, Desch, Wienemann]

[Flächer, Goebel, Haller, Höcker, Mönig, Stelzer]

# What SFitter does

- Set of measurements
  - LHC measurements:  
kinematic edges, thresholds, masses, mass differences  
cross sections, branching ratios
  - ILC measurements
  - Indirect Constraints  
electro-weak:  $M_W, \sin^2 \theta_W$ ;  $(g - 2)_\mu$   
flavour:  $\text{BR}(b \rightarrow s\gamma), \text{BR}(B_s \rightarrow \mu^+ \mu^-)$ ; dark matter:  $\Omega h^2$
  - or even ATLAS and CMS measurements separately
- Compare to theoretical predictions
  - Spectrum calculators: SoftSUSY, SuSPECT, ISASUSY  
[Allanach; Djouadi, Kneur, Moutaka; Baer, Paige, Protopopescu, Tata]
  - LHC cross sections: Prospino2 [Plehn et al.]
  - LC cross sections: MsmLib [Ganis]
  - Branching Ratios: SUSYHit (HDecay + SDecay) [Djouadi, Mühleitner, Spira]
  - micrOMEGAs [Bélanger, Boudjema, Pukhov, Semenov]
  - g-2 [Alexander, Stöckinger]
- Using as glue: SLHAio [Kreiss]

# Parameter Scans

- MSSM parameter space is high-dimensional:
  - SM: 3+ parameters ( $m_t, \alpha_s, \alpha, \dots$ )
  - mSUGRA: 5 parameters ( $m_0, m_{1/2}, A_0, \tan(\beta), \text{sgn}(\mu)$ )
  - General MSSM: 105 parameters
- On loop-level observables depend on every parameter  
Simple inversion of the relations not possible  
⇒ Parameter scans
- Error estimates on parameters in the minimum

# Parameter Scans

- MSSM parameter space is high-dimensional:
  - SM: 3+ parameters ( $m_t, \alpha_s, \alpha, \dots$ )
  - mSUGRA: 5 parameters ( $m_0, m_{1/2}, A_0, \tan(\beta), \text{sgn}(\mu)$ )
  - General MSSM: 105 parameters
- On loop-level observables depend on every parameter  
Simple inversion of the relations not possible  
 $\Rightarrow$  Parameter scans
- Error estimates on parameters in the minimum

Find best points (best  $\chi^2$ ) using different fitting techniques:

- Gradient search (Minuit)  $\left( \begin{array}{l} + \text{ Reasonably fast} \\ - \text{ Limited convergence, only best fit} \end{array} \right)$

# Parameter Scans

- MSSM parameter space is high-dimensional:
  - SM: 3+ parameters ( $m_t, \alpha_s, \alpha, \dots$ )
  - mSUGRA: 5 parameters ( $m_0, m_{1/2}, A_0, \tan(\beta), \text{sgn}(\mu)$ )
  - General MSSM: 105 parameters
- On loop-level observables depend on every parameter  
Simple inversion of the relations not possible  
 $\Rightarrow$  Parameter scans
- Error estimates on parameters in the minimum

Find best points (best  $\chi^2$ ) using different fitting techniques:

- Gradient search (Minuit)  $\left( \begin{array}{l} + \text{ Reasonably fast} \\ - \text{ Limited convergence, only best fit} \end{array} \right)$
- fixed Grid scan  $\left( \begin{array}{l} + \text{ scans complete parameter space} \\ - \text{ many points needed } (\mathcal{O}(e^N)) \end{array} \right)$

# Parameter Scans

- MSSM parameter space is high-dimensional:
  - SM: 3+ parameters ( $m_t, \alpha_s, \alpha, \dots$ )
  - mSUGRA: 5 parameters ( $m_0, m_{1/2}, A_0, \tan(\beta), \text{sgn}(\mu)$ )
  - General MSSM: 105 parameters
- On loop-level observables depend on every parameter  
Simple inversion of the relations not possible  
 $\Rightarrow$  Parameter scans
- Error estimates on parameters in the minimum

Find best points (best  $\chi^2$ ) using different fitting techniques:

- Gradient search (Minuit)  $\left( \begin{array}{l} + \text{ Reasonably fast} \\ - \text{ Limited convergence, only best fit} \end{array} \right)$
- fixed Grid scan  $\left( \begin{array}{l} + \text{ scans complete parameter space} \\ - \text{ many points needed } (\mathcal{O}(e^N)) \end{array} \right)$
- Weighted Markov Chains

# Markov Chains

## Markov Chain (MC):

- Sequence of points, chosen by an algorithm (Metropolis-Hastings), only depending on its direct predecessor
- Picks a set of "typical" points according to a potential  $V$  (e.g. inverse log-likelihood,  $1/\chi^2$ )
- Point density resembles the value of  $V$  (i.e. more points in region with high  $V$ )
- Scans high dimensional parameter spaces efficiently [Baltz, Gondolo 2004]
- mSUGRA MC scans with current exp. limits

[Allanach, Cranmer, Lester, Weber 2005-8; Roszkowski, Ruiz de Austra, Trotta 2006-8]

# Weighted Markov Chains

## Weighted Markov Chains:

Improved evaluation algorithm for binning:

[Plehn, MR]

- Weight points with value of  $V$ :
  - Take care of
    - Overcounting because point density is already weighted ( $\frac{\text{number of points}}{\sum_{\text{points}} 1/V(\text{point})}$ )  
[based on Ferrenberg, Swendsen 1988]
    - Correct account for regions with zero probability  
(maintain additional chain which stores points rejected because  $V(\text{point}) = 0$ )
- + Fast scans of high-dimensional spaces  $\mathcal{O}(N)$
  - + Does not rely on shape of  $\chi^2$  (no derivatives used)
  - + Can find secondary distinct solutions
  - Exact minimum difficult to find  $\Rightarrow$  Additional gradient fit
  - Bad choice of proposal function for next point leads to bad coverage of the space

# Experimental Input (Edges)

mSUGRA SPS1a as a benchmark point:

$m_0 = 100 \text{ GeV}$ ,  $m_{1/2} = 250 \text{ GeV}$ ,  $A_0 = -100 \text{ GeV}$ ,  $\tan \beta = 10$ ,  $\text{sgn } \mu = +1$ ,  $m_t = 171.4 \text{ GeV}$

LHC “experimental” data from cascade decays (best precision obtainable)

Measurement	Value ( GeV )	Errors ( GeV )	
		(stat)	(syst)
$(m_{llq}^{\max})$ :Edge( $\tilde{q}_L, \chi_2^0, \chi_1^0$ )	446.44	1.4	4.3
$(m_{llq}^{\min})$ :Thres( $\tilde{q}_L, \chi_2^0, \tilde{\mu}_R, \chi_1^0$ )	211.95	1.6	2.0
$(m_{lq}^{\text{low}})$ :Edge( $\tilde{c}_L, \chi_2^0, \tilde{\mu}_R$ )	316.51	0.9	3.0
$(m_{lq}^{\text{high}})$ :Edge( $\tilde{c}_L, \chi_2^0, \tilde{\mu}_R, \chi_1^0$ )	392.8	1.0	3.8
...	...	...	...

Theoretical Errors:

- mSUGRA: 3% for gluino and squark masses, 1% for all other sparticle masses
- MSSM: 1% for gluino and squark masses, 0.5% for all other sparticle masses
- $m_{h^0}$ : 2 GeV (unknown higher order terms)

# mSUGRA as a Toy Model

mSUGRA with LHC measurements (SPS1a kinematic edges):  
pick one set of "measurements", randomly smeared from the true values

Free parameters:

$m_0, m_{1/2}, \tan(\beta), A_0, \text{sgn}(\mu), m_t$

SFitter output 1:

Fully-dimensional exclusive likelihood map

(colour:

minimum  $\chi^2$  over all unseen parameters)

SFitter output 2:

Ranked list of minima:

	$\chi^2$	$m_0$	$m_{1/2}$	$\tan(\beta)$	$A_0$	$\mu$	$m_t$
SPS1a		100.0	250.0	10.0	-100.0	+	171.4
1)	0.09	102.0	254.0	11.5	-95.2	+	172.4
2)	1.50	104.8	242.1	12.9	-174.4	-	172.3
3)	73.2	108.1	266.4	14.6	742.4	+	173.7
4)	139.5	112.1	261.0	18.0	632.6	-	173.0

# Bayesian or Frequentist?

SFitter provides full-dimensional log-likelihood map  
→ "project" onto plotable 1- or 2-dimensional spaces

Bayesian:

Marginalisation of  $\chi^2$  in all other directions

Frequentist:

Profile likelihood: Value of bin is value of smallest  $\chi^2$  occurring in this bin

# Bayesian or Frequentist?

SFitter provides full-dimensional log-likelihood map  
→ "project" onto plotable 1- or 2-dimensional spaces

Bayesian:

Marginalisation of  $\chi^2$  in all other directions

Frequentist:

Profile likelihood: Value of bin is value of smallest  $\chi^2$  occurring in this bin

Different methods answer different questions.

⇒ Bayesian **and** Frequentist!

Everybody can choose his/her favourite analysis . . .

# Purely high-scale model

$m_0, m_{1/2}, A_0$  defined at the GUT-scale  $\Leftrightarrow \tan(\beta)$  defined at the weak scale

$\Rightarrow$  Replace  $\tan(\beta)$  with high-scale quantity  $B$

$\Rightarrow$  Flat prior in  $B$  yields prior  $\propto \frac{1}{\tan(\beta)^2}$

SPS1a with LHC kinematic edges ( $\tan(\beta)$  vs.  $1/\chi^2$ ):

flat  $B$  prior

flat  $\tan(\beta)$  prior

Bayesian:

Large influence of choice of prior

Choosing flat  $B$  prior strongly favours low values of  $\tan(\beta)$ .

Frequentist:

Two plots should be identical (no prior in  $\chi^2$  calculation)

Indirect influence via Markov Chain proposal function

# Error determination

Treatment of errors:

- All experimental errors are Gaussian

$$\sigma_{\text{exp}}^2 = \sigma_{\text{stat}}^2 + \sigma_{\text{syst}(j)}^2 + \sigma_{\text{syst}(l)}^2$$

- Systematic errors from jet ( $\sigma_{\text{syst}(j)}$ ) and lepton energy scale ( $\sigma_{\text{syst}(l)}$ ) assumed 99% correlated each

- Theory error added as box-shaped (RFit scheme [Hoecker, Lacker, Laplace, Lediberder])

$$\Rightarrow -2 \log L \equiv \chi^2 = \sum_{\text{measurements}} \begin{cases} 0 & \text{for } |x_{\text{data}} - x_{\text{pred}}| < \sigma_{\text{theo}} \\ \left( \frac{|x_{\text{data}} - x_{\text{pred}}| - \sigma_{\text{theo}}}{\sigma_{\text{exp}}} \right)^2 & \text{for } |x_{\text{data}} - x_{\text{pred}}| \geq \sigma_{\text{theo}} \end{cases}$$

⇒ Parameter errors:

	SPS1a	$\Delta_{\text{zero}}^{\text{theo-exp}}$	$\Delta_{\text{zero}}^{\text{theo-exp}}$	$\Delta_{\text{gauss}}^{\text{theo-exp}}$	$\Delta_{\text{flat}}^{\text{theo-exp}}$
		LHC masses	LHC edges		
$m_0$	100	4.11	0.50	2.97	2.17
$m_{1/2}$	250	1.81	0.73	2.99	2.64
$\tan \beta$	10	1.69	0.65	3.36	2.45
$A_0$	-100	36.2	21.2	51.5	49.6
$m_t$	171.4	0.94	0.26	0.89	0.97

⇒ Use kinematic edges for parameter determination instead of masses

# Weak-scale MSSM

- No need to assume specific SUSY-breaking scenario  
⇒ SUSY-breaking mechanism should be induced from data
- Use of Markov Chains makes scanning the 19-dimensional parameter space feasible
- Lack of sensitivity on one parameter does not slow down the scan  
(no need to fix parameters)
- Same SFitter output as before: Minima list and Likelihood map

# Weak-scale MSSM

- No need to assume specific SUSY-breaking scenario  
⇒ SUSY-breaking mechanism should be induced from data
- Use of Markov Chains makes scanning the 19-dimensional parameter space feasible
- Lack of sensitivity on one parameter does not slow down the scan  
(no need to fix parameters)
- Same SFitter output as before: Minima list and Likelihood map

Full scan of 19D parameter space challenging

Four-step procedure yields better and faster results:

- Weighted-Markov-Chain run with flat pdf over full parameter space  
5 best points additionally minimised  
(full scan, no bias on starting point)

# Weak-scale MSSM

- No need to assume specific SUSY-breaking scenario  
⇒ SUSY-breaking mechanism should be induced from data
- Use of Markov Chains makes scanning the 19-dimensional parameter space feasible
- Lack of sensitivity on one parameter does not slow down the scan  
(no need to fix parameters)

# Degenerate Solutions

- In total 19 parameters constrained by 22 measurements
- Measurements constructed from only 15 underlying masses
- $\Rightarrow$  Complete determination of parameter set not possible
- Five parameters not well constrained
  - $m_A$ 
    - $\leftarrow$  no heavy Higgses measurable
  - $M_{\tilde{t}_R}$
  - $A_t$ 
    - $\leftarrow$  stop sector parameters do not enter edge measurements
  - $M_{\tilde{\tau}_L}$  or  $M_{\tilde{\tau}_R}$ 
    - $\leftarrow$  only the lighter stau measured
  - $\tan \beta$ 
    - $\leftarrow$  change can always be accommodated by rotating  $M_1, M_2, M_{\tilde{q}_3}, \dots$
- Single common link:  $m_{h^0}$
- $\Rightarrow$  4-dimensional hyperplane in parameter space undetermined
- Can still assign errors to some of the badly determined parameters

# Error analysis

- Technical procedure as in mSUGRA case:
  - 10000 smeared data sets
  - Minimum determined for each data set individually
  - Error determined from fit with Gaussian
- Most constrained parameters determinable with  $\sim 5\%$  accuracy
- Inclusion of theory errors leads to an increase of factor 2 on the parameter errors
- ILC data complementary to LHC
- Combination of the two experiments allows for precise determination of all parameters

	LHC		ILC		LHC+ILC	SPS1a
$M_1$	$102.1 \pm 7.8$		$103.0 \pm 1.1$		$103.1 \pm 0.84$	103.1
$M_{\tilde{e}_R}$	$135.0 \pm 8.3$		$135.8 \pm 0.81$		$135.9 \pm 0.77$	135.8
$m_A$	$406.3 \pm \mathcal{O}(10^3)$		$393.8 \pm 1.6$		$393.9 \pm 1.6$	394.9
$M_{\tilde{t}_R}$	$415.8 \pm \mathcal{O}(10^2)$		$440.0 \pm \mathcal{O}(4 \cdot 10^2)$		$410.7 \pm 48.4$	408.3

# Dark Matter

Content of the universe:

- 73% Dark energy
- 4% Ordinary matter
- 23% Dark matter

[NASA/WMAP  
Science Team ]

MSSM:  $\chi_1^0$  as LSP ideal candidate for cold dark matter (CDM): massive, weakly interacting

- SFitter: Determine Lagrangian parameters  $\Rightarrow$  Spectrum and couplings
- e.g. micrOMEGAs: Calculate relic density  $\Omega_{\text{CDM}} h^2 = n_{\text{LSP}} m_{\text{LSP}}$

[Bélanger et al.]

- $\Rightarrow$  Prediction of  $\Omega_{\text{CDM}} h^2$   
LHC :  $\Omega_{\text{CDM}} h^2 = 0.1906 \pm 0.0033$   
LHC+ILC:  $\Omega_{\text{CDM}} h^2 = 0.1910 \pm 0.0003$   
(improvement by one order of magnitude)

- Compare with experiment  
(Measurement of the fluctuations of the cosmic microwave background):

WMAP:  $\Omega_{\text{CDM}} h^2 = 0.1277 \pm 0.008$  [[astro-ph/0603449](https://arxiv.org/abs/astro-ph/0603449)]

Planck:  $\Omega_{\text{CDM}} h^2 = ? \pm 0.0016$

# Summary & Outlook

The SFitter program:

- High-dimensional parameter scans important to determine Lagrangian parameters from observables
- Improved Weighted Markov Chain algorithm can do this efficiently
- Two types of SFitter output: Likelihood map and list of best points

SUSY analysis:

- mSUGRA:
  - Can reconstruct SPS1a from (simulated) LHC data
  - Bayesian output significantly dependent on priors
- weak-scale MSSM:
  - Reconstruction works as well
  - Degenerate solutions in gaugino-higgsino-sector and
  - General underdetermination of parameter space, in particular  $\tan \beta$
- Test of Dark-Matter hypothesis seems possible
- SFitter (despite its name) not tied to SUSY  
→ extend to other models/problems

# Backup Slides

# Improving on $\tan \beta$

- difficult even in mSUGRA

Analysis with LHC kinematic edges as before, but now assume mSUGRA scenario:

	SPS1a	$\Delta_{\text{zero}}^{\text{theo-exp}}$	$\Delta_{\text{zero}}^{\text{theo-exp}}$	$\Delta_{\text{gauss}}^{\text{theo-exp}}$	$\Delta_{\text{flat}}^{\text{theo-exp}}$
		LHC masses	LHC edges		
$\tan \beta$	10	1.69	0.65	3.36	2.45

profile likelihood:

# Improving on $\tan \beta$

- difficult even in mSUGRA
- LHC rates:  $\tan \beta$  from heavy Higgses (for large  $\tan \beta$ )  
 $\propto (\tan \beta)^2$   
→ in general: challenging  
→ for SPS1a: no heavy Higgses observed

[Kinnunen, Lehti, Moortgat, Nikitenko, Spira]

# Improving on $\tan \beta$

- difficult even in mSUGRA
- LHC rates:  $\tan \beta$  from heavy Higgses (for large  $\tan \beta$ ) [Kinnunen, Lehti, Moortgat, Nikitenko, Spira]
- $B_s \rightarrow \mu^+ \mu^-$  [Jäger, Spannowsky, SFitter]
  - $\propto (\tan \beta)^6$
  - LHCb will be able to probe the SM value
  - Errors largely theory-dominated (main source:  $f_{B_s}$  from lattice simulations)
  - In a simple proof-of-concept analysis:  $\tan \beta = 30 \pm 6.5$

# Improving on $\tan \beta$

- difficult even in mSUGRA
- LHC rates:  $\tan \beta$  from heavy Higgses (for large  $\tan \beta$ ) [Kinnunen, Lehti, Moortgat, Nikitenko, Spira]
- $B_s \rightarrow \mu^+ \mu^-$  [Jäger, Spannowsky, SFitter]
- anomalous magnetic moment of the muon [review: Stöckinger]

# $\tan \beta$ from other sectors

Electro-weak sector: Anomalous Magnetic Moment of the Muon  $(g - 2)_\mu$

[Alexander, Kreiss, SFitter]

- Currently  $3.4\sigma$  deviation from Standard Model
- Leading order  $\simeq 130 \cdot 10^{-11} \tan \beta \operatorname{sgn}(\mu) \left( \frac{100 \text{ GeV}}{M_{\text{SUSY}}} \right)^2$
- $\Rightarrow$  Favours one sign of  $\mu \rightarrow +$
- $\Rightarrow$  Linearly sensitive on  $\tan \beta$

	LHC	LHC $\otimes (g - 2)_\mu$	SPS1a
<b><math>\tan \beta</math></b>	<b><math>10.0 \pm 4.5</math></b>	<b><math>10.3 \pm 2.0</math></b>	<b>10.0</b>
$M_1$	$102.1 \pm 7.8$	$102.7 \pm 5.9$	103.1
$M_2$	$193.3 \pm 7.8$	$193.2 \pm 5.8$	192.9
$M_3$	$577.2 \pm 14.5$	$578.2 \pm 12.1$	577.9
$\mu$	$350.5 \pm 14.5$	$352.5 \pm 10.8$	353.7
$M_{\tilde{\mu}_R}$	$135.0 \pm 8.3$	$135.6 \pm 6.3$	135.8
$M_{\tilde{q}_R}$	$507.3 \pm 17.5$	$507.6 \pm 15.8$	508.1

$\Rightarrow$  Need to combine information on  $\tan \beta$  from all sectors

# Testing Unification

Apparent unification of gauge coupling parameters in the MSSM

Question arises: Do other parameters unify as well?

⇒ Should be tested by bottom-up running from weak scale to Planck scale

⇒ Can give hints about supersymmetry breaking

(e.g. test scalar-mass sum rules with a sliding scale)

[Schmaltz et al.]

Bottom-up running of gaugino masses and 3rd-generation sfermion masses:

$$M_{\tilde{\tau}_R}, M_{\tilde{\tau}_L}, M_{\tilde{t}_R}, M_{\tilde{b}_R}, M_{\tilde{q}_{3L}}; \Delta M_3 = -10 \text{ GeV}$$

# Testing Unification

Apparent unification of gauge coupling parameters in the MSSM

Question arises: Do other parameters unify as well?

⇒ Should be tested by bottom-up running from weak scale to Planck scale

⇒ Can give hints about supersymmetry breaking

(e.g. test scalar-mass sum rules with a sliding scale)

[Schmaltz et al.]

Bottom-up running of gaugino masses and 3rd-generation sfermion masses:

$M_{\tilde{\tau}_R}, M_{\tilde{\tau}_L}, M_{\tilde{t}_R}, M_{\tilde{t}_L}, M_{\tilde{q}_{3L}}; \Delta M_3 = -10 \text{ GeV}$

# Error determination

Minuit output not usable for flat theory errors:

- Migrad function depends on parabolic approximation
- Cannot determine  $\Delta\chi^2$  for Minos to yield 68% CL intervals

⇒ Need more general approach

- Perform 10,000 toy experiments with measurements smeared around correct value
- Minimise each toy experiment
- Plot resulting distribution of parameter points and fit with Gaussian

Flat theory errors

Gaussian theory errors

# Weak-scale MSSM

- No need to assume specific SUSY-breaking scenario  
⇒ SUSY-breaking mechanism should be induced from data
- Use of Markov Chains makes scanning the 19-dimensional parameter space feasible
- Lack of sensitivity on one parameter does not slow down the scan  
(no need to fix parameters)
- Same SFitter output as before: Minima list and Likelihood map

MSSM using SPS1a spectrum and LHC kinematic edges:  
(Bayesian, full parameter space)

# Search Strategy (1)

Full scan of 19D parameter space challenging

Four-step procedure yields better and faster results:

- Weighted-Markov-Chain run with flat pdf over full parameter space
- 5 best points additionally minimised (full scan, no bias on starting point)

Correlations not aligned with parameters  $\Rightarrow$  washed out in plots

# Search Strategy (2)

Full scan of 19D parameter space challenging

Four-step procedure yields better and faster results:

- Weighted-Markov-Chain run with flat pdf over full parameter space  
5 best points additionally minimised  
(full scan, no bias on starting point)
- Weighted-Markov Chain with flat pdf on Gaugino-Higgsino subspace:  
 $M_1, M_2, M_3, \mu, \tan \beta, m_t$   
Additional Minuit run with 15 best solutions
