

Higgs Couplings at the LHC and beyond

Michael Rauch | 19th SFB/TR9 meeting, Aachen, Mar 2013

INSTITUTE FOR THEORETICAL PHYSICS

Higgs properties

Verify nature of observed resonance

↔ “Higgs” properties

- spin-0 particle
 - spin-1 excluded by $H \rightarrow \gamma\gamma$
 - spin-2: look at angular correlations
- CP-nature
 - SM-Higgs CP-even; extended Higgs sectors also CP-odd or mixed states
 - look at angular correlations

[Landau-Yang theorem]

[Zeppenfeld *et al.* ; Choi *et al.* ; Godbole *et al.* ; Hagiwara, Mawatari, Li; Englert *et al.* ; Ellis *et al.* ; Frank, MR, Zeppenfeld; Alves; Boughezal *et al.* ; ...]

→ checked by ATLAS and CMS

e.g. CMS WW 0-jet analysis, $m_{\ell\ell}-m_T$ -plane

background

Higgs signal

Spin-2 signal

data

⇒ CP-odd and spin-2 currently disfavoured at 1 – 2 σ level

Couplings:

SM prediction fixed by already known quantities

- unitarity in $W_L W_L \rightarrow W_L W_L$ scattering
→ fixed coupling $g_{WWH} \propto m_W$
- fermion masses
→ $g_{f\bar{f}H} \propto m_f$
- Higgs self-couplings
determine shape of Higgs potential via trilinear and quartic couplings
SM: $V = \mu^2 |\Phi|^2 + \lambda |\Phi|^4 + \text{const.}$
new scale Λ : $V = \sum_{n \geq 0} \frac{\lambda^n}{\Lambda^{2n}} \left(|\Phi|^2 + \frac{v^2}{2} \right)^{2+n}$
→ very challenging for LHC (and ILC)

[Djouadi *et al.* ; Plehn *et al.* ; Baur *et al.* ; MR *et al.* ; Binoth *et al.* ; Englert *et al.* ; Baglio *et al.* ; ...]

↔ New-physics models modifying Higgs couplings

- Additional Higgs particles (Higgs portal, THDM, ...)
 - Composite Higgs models
 - Supersymmetry
- Expected deviations: $\mathcal{O}(10\%)$

[Gupta, Rzehak, Wells]

Generalized Higgs sector

How well can we determine the SM Higgs couplings?

Can we distinguish a non-Standard-Model-like Higgs sector?

- Theory: **Standard Model plus free Higgs couplings**

Couplings from modified version of HDecay

[Djouadi, Kalinowski, Mühlleitner, Spira]

- For Higgs couplings present in the Standard Model $x = W, Z, t, b, \tau$

$$g_{xxH} \equiv g_x \longrightarrow g_x^{\text{SM}} (1 + \Delta_x) \quad (\rightarrow \Delta = -2 \text{ means sign flip})$$

- For loop-induced Higgs couplings $x = \gamma, g$

$$g_x \longrightarrow g_x^{\text{SM}} (1 + \Delta_x^{\text{SM}} + \Delta_x)$$

where g_x^{SM} : (loop-induced) coupling in the Standard Model

Δ_x^{SM} : contribution from modified tree-level couplings
to Standard-Model particles

Δ_x : additional (dimension-five) contribution

- Ratios $\frac{g_x}{g_y} = \frac{g_x^{\text{SM}}}{g_y^{\text{SM}}} (1 + \Delta_{x/y})$

- Neglecting couplings only available from high-luminosity analyses

$(g_\mu, g_{HZ\gamma}^{\text{eff}}, g_{HHHH}, g_{HHHHH})$

- Δ_H : single parameter modifying all (tree-level) couplings

- Total width

$$\Gamma_{\text{tot}} = \Sigma_{\text{obs}} \Gamma_x < 2 \text{ GeV} \quad (\text{plus generation universality})$$

- Electro-weak corrections not yet relevant

for later consistency: QCD corrections scale with couplings, EW ones not

Algorithms:

- Weighted Markov chain
- Cooling Markov chain (\sim simulated annealing)
- Modified gradient fit (Minuit)
- Grid scan
- Nested Sampling [Skilling; Feroz, Hobson]

Errors:

- three types:
 - Gaussian – arbitrary correlations possible (\rightarrow systematic errors)
 - Poisson
 - box-shaped (RFit) [CKMFitter]
- assignment as in exp. studies
- adaption to likelihood input easy

Output of SFitter:

- fully-dimensional log-likelihood map
- one- and two-dimensional distributions via
 - marginalization (Bayesian)
 - profile likelihood (Frequentist)
- list of best points

Higgs Couplings after Moriond 2013

7 TeV $\mathcal{L} = 4.6\text{-}5.1 \text{ fb}^{-1}$

⊗ 8 TeV $\mathcal{L} = 12\text{-}21 \text{ fb}^{-1}$

- background expectations, exp. errors, etc. from analyses
- cross-checked with exclusion and signal-strength plots

CMS $\gamma\gamma$ and $\tau\tau$ CONF-notes not yet available.

⇒ Results shown here only with global signal-strength data.

Δ_V vs. Δ_f

SM hypothesis
(bkgd. + SM-strength signal injected)

Expected 2012 results:

- Correct solution around SM value
 $\Delta = 0$
- Secondary solution
for opposite fermion coupling
→ photon coupling enhanced
- $\sim 2.5\sigma$ discrimination power
between both signs

Δ_V vs. Δ_f

SM hypothesis
(bkgd. + SM-strength signal injected)

measured data

Expected 2012 results:

- Correct solution around SM value $\Delta = 0$
- Secondary solution for opposite fermion coupling \rightarrow photon coupling enhanced
- $\sim 2.5\sigma$ discrimination power between both signs

2012 results:

- similar to expectation
- opposite-sign solution clearly disfavoured

Δ_W vs. Δ_t

SM hypothesis

(bkgd. + SM-strength signal injected)

Expected 2012 results:

- Correct solution around SM value
 $\Delta = 0$
- Secondary solution
for flipped top Yukawa coupling
→ photon coupling enhanced
- Large- Δ_t solution of 2011 killed
by $t\bar{t}H$, $H \rightarrow b\bar{b}$ measurement

Δ_W vs. Δ_t

SM hypothesis
(bkgd. + SM-strength signal injected)

measured data

Expected 2012 results:

- Correct solution around SM value
 $\Delta = 0$
- Secondary solution for flipped top Yukawa coupling
→ photon coupling enhanced
- Large- Δ_t solution of 2011 killed by $t\bar{t}H, H \rightarrow b\bar{b}$ measurement

2012 results:

- similar to expectation
- flipped-top coupling basically equal log-likelihood
- small remnant of large- Δ_t solution

Δ_W vs. Δ_τ

SM hypothesis

Expected 2012 results:

- Clear indication of non-vanishing $H_{\tau\tau}$ coupling

Δ_W vs. Δ_τ

SM hypothesis

measured data

Expected 2012 results:

- Clear indication of non-vanishing $H_{\tau\tau}$ coupling
- Finally seen
- First direct evidence for coupling to fermions!

Δ_W vs. Δ_τ

SM hypothesis

measured data

Expected 2012 results:

- Clear indication of non-vanishing $H_{\tau\tau}$ coupling
- Finally seen
- First direct evidence for coupling to fermions!

Best-fitting solutions:

Δ_W	Δ_Z	Δ_t	Δ_b	Δ_τ	$\chi^2/\text{d.o.f.}$	$\chi^2(\text{SM}) = 16.4$
-0.11	-0.04	-0.20	-0.27	-0.04	15.8/58	
-0.26	-0.02	-1.70	-0.30	0.03	16.8/58	

Global view

Independent contribution to photon coupling Δ_γ

$\Delta_W - \Delta_\gamma$ measured data

$\Delta_t - \Delta_\gamma$ measured data

Standard Model-like solution plus secondary flipped-sign solutions

(Anti-)correlations between parameters as expected

No surprising new features

■ One year ago ...

Impact of subset analysis

[SFitter]

Top to bottom: ● $VH, H \rightarrow b\bar{b}$ subset analysis with full strength

● sensitivity reduced by 50%

● subset analysis removed

↔ No test of subset analysis with data yet

[Butterworth, Davison, Rubin, Salam; ATLAS-MC]

Additional decays into “invisible” final states possible

$$\Gamma_{\text{tot}} = \Gamma_{\text{tot}}^{\text{SM}} + \Gamma_{\text{inv}} \equiv \Gamma_{\text{tot}}^{\text{SM}} (1 + \Delta\Gamma)$$

Can be compensated by global scaling of couplings

$$\sigma \cdot BR = \frac{\Delta_H^2}{1 + \frac{\Delta\Gamma}{\Delta_H^2}} (\sigma \cdot BR)_{\text{SM}}$$

- Invisible Higgs decays actually observable
 - Vector-Boson Fusion: tagging jets plus missing E_T [Eboli, Zeppenfeld]
 - WH/ZH : recoil against nothing [Choudhury, Roy; Godbole, Guchait, Mazumdar, Moretti, Roy; Englert, Spannowsky, Wymant]
- Unobservable decays into particles with large backgrounds (like $H \rightarrow$ jets)
e.g. increased ccH coupling (corresponding to 15.4 GeV Yukawa coupling)

Invisible vs. Unobserved

- Unobservable decays into particles with large backgrounds (like $H \rightarrow$ jets)
e.g. increased ccH coupling (corresponding to 15.4 GeV Yukawa coupling)
 $\mathcal{L} = 30 \text{ fb}^{-1}$, SM data / increased ccH / increased ccH plus free width

Invisible vs. Unobserved

- Unobservable decays into particles with large backgrounds (like $H \rightarrow$ jets)
e.g. increased ccH coupling (corresponding to 15.4 GeV Yukawa coupling)
 $\mathcal{L} = 30 \text{ fb}^{-1}$, SM data / increased ccH / increased ccH plus free width

Invisible vs. Unobserved

- Unobservable decays into particles with large backgrounds (like $H \rightarrow$ jets)
e.g. increased ccH coupling (corresponding to 15.4 GeV Yukawa coupling)
 $\mathcal{L} = 30 \text{ fb}^{-1}$, SM data / increased ccH / increased ccH plus free width

Invisible vs. Unobserved

- Unobservable decays into particles with large backgrounds (like $H \rightarrow \text{jets}$)
 e.g. increased ccH coupling (corresponding to 15.4 GeV Yukawa coupling)
 $\mathcal{L} = 30 \text{ fb}^{-1}$, SM data / increased ccH / increased ccH plus free width

LHC in the future

LHC high-luminosity run: 14 TeV, 3000 fb⁻¹
Standard Model hypothesis

- extrapolation done blindly (only stat. improvements) starting from MC expectation at 14 TeV, 30 fb⁻¹
- full set including effective couplings

- gain factor less than 3 (30 → 300 fb⁻¹), $\sqrt{3}$ (300 → 1000 fb⁻¹, 1000 → 3000 fb⁻¹)
- ⇒ statistical scaling does not apply any longer
- best obtainable precision $\simeq 10\%$
- all couplings limited by systematic and theory error

Linear Collider

Linear Collider:

proposed first run: $\sqrt{S} = 250 \text{ GeV}$, $L = 250 \text{ fb}^{-1}$,
 upgrade to $\sqrt{S} = 500 \text{ GeV}$, $L = 500 \text{ fb}^{-1}$

ILC measurements (from DBD draft)

[Peskin (ed.) *et al.*]

Main production mode ZH

Allows measuring inclusive ZH cross section via recoil technique
 (use all events where Z decay products kinematically compatible with ZH production; H decay products stay unobserved)

WW -fusion channel

Important ingredient to reconstruct total width

Combine four measurements

- 1 Higgs-strahlung inclusive (σ_{ZH})
- 2 Higgs-strahlung, $H \rightarrow b\bar{b}$ (σ_{Zbb})
- 3 Higgs-strahlung, $H \rightarrow WW$ (σ_{ZWW})
- 4 WW -fusion with $H \rightarrow b\bar{b}$ ($\sigma_{\nu\nu bb}$)

and four unknowns Δ_W , Δ_Z , Δ_b , and Γ_{tot} :

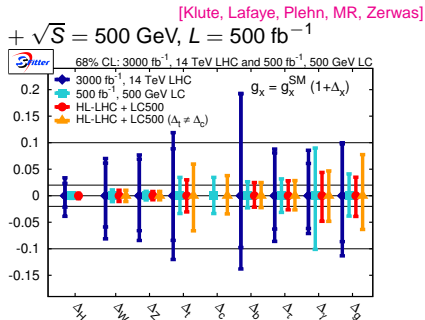

$$\Gamma_{\text{tot}} \leftarrow \frac{\sigma_{\nu\nu bb} / \sigma_{Zbb}}{\sigma_{ZWW} / \sigma_{ZH}} \times \sigma_{ZH}$$

[Klute, Lafaye, Plehn, MR, Zerwas]

- reminder: $\Delta_t = \Delta_c$
(generation universality)
- LHC: no Δ_c
(no obs. channel)
- ILC: no Δ_t
(below $t\bar{t}H$ threshold)

- dramatic improvement on Δ_Z, Δ_b
- complementary: combination better than each alone
- testing $\Delta_t \stackrel{?}{=} \Delta_c$ possible

- dramatic improvement on Δ_Z, Δ_b
- complementary: combination better than each alone
- testing $\Delta_t \stackrel{?}{=} \Delta_c$ possible

+ 500 GeV run: ILC precision surpasses LHC everywhere

Conclusions & Outlook

- Determining the Higgs-boson couplings important for our understanding of electroweak symmetry breaking
→ Standard Model with effective Higgs couplings
- All errors including correlations fully implemented
- Already wealth of measurements from LHC
- Precision on single-parameter modifier $\Delta_H \simeq 10\%$ already now
- SM Higgs Boson good explanation of observed resonance

- Need to scan high-dimensional parameter space
- \Rightarrow SFitter [Lafaye, Plehn, MR, Zerwas]
- General Higgs couplings from modified version of HDecay [Djouadi, Kalinowski, Spira]
- Three scanning techniques:
 - Weighted Markov Chain
 - Cooling Markov Chain (equivalent to simulated annealing)
 - Gradient Minimisation (Minuit)
 - Nested Sampling [Skilling; Feroz, Hobson]
- Output of SFitter:
 - Fully-dimensional log-likelihood map
 - Reduction to plotable one- or two-dimensional distributions via both
 - Bayesian (marginalisation) or
 - Frequentist (profile likelihood) techniques
 - List of best points
- Also successfully used for SUSY parameter extraction studies [partly in coll. with Adam, Kneur, Turlay]

Last line obtained using subjet techniques ([Butterworth, Davison, Rubin, Salam]),
 theoretical results confirmed by ATLAS ([ATL-PHYS-PUB-2009-088])
 (stricter cuts, statistical significance basically unchanged)

In the future

2012, 2014, ... (assuming $m_H = 125$ GeV)

Scenarios: 2012_{low}: (7.5 fb⁻¹, 8 TeV) ⊗ (5 fb⁻¹, 7 TeV)
 2012_{high}: (17.5 fb⁻¹, 8 TeV) ⊗ (5 fb⁻¹, 7 TeV)
 2014: (30 fb⁻¹, 14 TeV)

Standard Model hypothesis

Extrapolation 7→8 TeV done blindly

(only statistical improvements, based on 2011 measurements)

- VBF measurements giving important information
- $t\bar{t}H$ and $H \rightarrow b\bar{b}$ measurements
- g_g and g_γ accessible independently

⇒ exciting prospects

Additional hidden sector as singlet under SM gauge groups

[Binoth, van der Bij; Hill, van der Bij; Schabinger, Wells; Patt, Wilczek; ...]

Only possible connection to SM:

$$\mathcal{L} \propto \Phi_s^\dagger \Phi_s \Phi_h^\dagger \Phi_h$$

$\Phi_{s/h}$: Higgs field of SM/hidden sector

Electro-weak symmetry breaking:

$$\phi_{s/h} \rightarrow (v_{s/h} + H_{s/h})/\sqrt{2}$$

H_s and H_h mix into mass eigenstates:

$$\begin{pmatrix} H_1 \\ H_2 \end{pmatrix} = \begin{pmatrix} \cos \chi & \sin \chi \\ -\sin \chi & \cos \chi \end{pmatrix} \begin{pmatrix} H_s \\ H_h \end{pmatrix}$$

Modifications for H_1 : ($\cos \chi \hat{=} \Delta_H$)

$$\sigma = \cos^2 \chi \cdot \sigma^{\text{SM}}$$

$$\Gamma_{\text{vis}} = \cos^2 \chi \cdot \Gamma_{\text{vis}}^{\text{SM}}$$

$$\Gamma_{\text{inv}} = \cos^2 \chi \cdot \Gamma_{\text{inv}}^{\text{SM}} + \Gamma_{\text{hid}}$$

($\Gamma_{\text{inv}}^{\text{SM}}$: Decay $H \rightarrow ZZ \rightarrow 4\nu$ (negligible))

similarly for H_2 with $\cos \chi \leftrightarrow \sin \chi$ plus possibly $\Gamma_2^{HH} : H_2 \rightarrow H_1 H_1$

The Higgs Portal

Fit of $\cos^2 \chi_{\text{fit}}$ without constraints (14 TeV, 30 fb^{-1})

[Bock, Lafaye, Plehn, MR, D. Zerwas, P.M. Zerwas]

- No invisible decay modes

\Rightarrow If $\cos^2 \chi_{\text{th}} < 0.6$ can exclude SM at the 95% CL with 30 fb^{-1}

- Measuring invisible decays in VBF-Higgs production

Signature: Two VBF-jets plus missing E_T

[Eboli, Zeppenfeld; MC-study: ATLAS]

$$\Gamma_{\text{hid}} = \sin^2 \chi \cdot \Gamma_{\text{tot}}^{\text{SM}} \quad (\text{rhs: } \cos^2 \chi_{\text{th}} = 0.6)$$

[C. Englert, Plehn, Rauch, D. Zerwas, P.M. Zerwas]

- bounds are determined by measurement of twin ratios

$$\left(\frac{\Gamma_p \Gamma_d}{\Gamma_{\text{tot}}} \right) / \left(\frac{\Gamma_p \Gamma_d}{\Gamma_{\text{tot}}} \right)^{\text{SM}} = (\sigma_p \times \text{BR}_d) / (\sigma_p \times \text{BR}_d)^{\text{SM}}$$

$$\frac{\sigma(pp \rightarrow H_1 \rightarrow F)}{\sigma(pp \rightarrow H_1 \rightarrow F)^{\text{SM}}} = \frac{\cos^2 \chi}{1 + \tan^2 \chi (\Gamma_1^{\text{hid}} / \Gamma_{\text{tot},1}^{\text{SM}})} \leq \mathcal{R}$$

$$\frac{\sigma(pp \rightarrow H_1 \rightarrow \text{inv})}{\sigma(pp \rightarrow H_1)^{\text{SM}}} = \frac{\sin^2 \chi (\Gamma_1^{\text{hid}} / \Gamma_{\text{tot},1}^{\text{SM}})}{1 + \tan^2 \chi (\Gamma_1^{\text{hid}} / \Gamma_{\text{tot},1}^{\text{SM}})} \leq \mathcal{J}$$

- additional constraint: electroweak precision data (dots: compatible points)

Example: $M_{H_1} = 155 \text{ GeV}$
 $\Rightarrow \mathcal{R} \lesssim 0.4 \text{ @ } 95\% \text{ CL}$

- bound weakened by invisible decays
- whole area left of it still possible
- significant improvement with higher statistics

[C. Englert, Plehn, Rauch, D. Zerwas, P.M. Zerwas]

- bounds are determined by measurement of twin ratios

$$\left(\frac{\Gamma_p \Gamma_d}{\Gamma_{\text{tot}}} \right) / \left(\frac{\Gamma_p \Gamma_d}{\Gamma_{\text{tot}}} \right)^{\text{SM}} = (\sigma_p \times \text{BR}_d) / (\sigma_p \times \text{BR}_d)^{\text{SM}}$$

$$\frac{\sigma(pp \rightarrow H_1 \rightarrow F)}{\sigma(pp \rightarrow H_1 \rightarrow F)^{\text{SM}}} = \frac{\cos^2 \chi}{1 + \tan^2 \chi (\Gamma_1^{\text{hid}} / \Gamma_{\text{tot},1}^{\text{SM}})} \leq \mathcal{R}$$

$$\frac{\sigma(pp \rightarrow H_1 \rightarrow \text{inv})}{\sigma(pp \rightarrow H_1)^{\text{SM}}} = \frac{\sin^2 \chi (\Gamma_1^{\text{hid}} / \Gamma_{\text{tot},1}^{\text{SM}})}{1 + \tan^2 \chi (\Gamma_1^{\text{hid}} / \Gamma_{\text{tot},1}^{\text{SM}})} \leq \mathcal{J}$$

- additional constraint: electroweak precision data (dots: compatible points)

- Standard Model: limit $\mathcal{R} \rightarrow 1$
- quantify coincidence by possible deviations left
- (invisible decays hard at LHC: \rightarrow Linear Collider)

[Giudice, Grojean, Pomarol, Rattazzi; Espinosa, Grojean, Mühlleitner]

Higgs pseudo-Goldstone boson of new strongly interacting sector
Modifications parametrized by $\xi = (v/f)^2$ (f : Goldstone scale)

- MCHM4:

Scaling of all couplings with $\sqrt{1-\xi}$
 \Rightarrow Identify $\cos^2 \chi = 1 - \xi$
 $\Gamma_{\text{hid}} = 0$

- MCHM5:

Scaling:

$$g_{VVH} = g_{VVH}^{\text{SM}} \cdot \sqrt{1-\xi}$$

$$g_{\bar{f}fH} = g_{\bar{f}fH}^{\text{SM}} \cdot \frac{1-2\xi}{\sqrt{1-\xi}}$$

Significant and observable deviations also in Higgs self-couplings

[Gröber, Mühlleitner]

[Bock, Lafaye, Plehn, MR, D. Zerwas, P.M. Zerwas]

Secondary solutions appear (sign of $f\bar{f}H$ coupling)

$m_H = 120$ GeV

$m_H = 160$ GeV

$m_H = 200$ GeV

$\mathcal{L} = 300$ fb $^{-1}$

Gluon fusion $H \rightarrow \gamma\gamma$

$WH/ZH, H \rightarrow b\bar{b}$

Not a true degeneracy

→ Each (smeared) toy experiment has unique solution

[Bock, Lafaye, Plehn, MR, D. Zerwas, P.M. Zerwas]

Secondary solutions appear (sign of $f\bar{f}H$ coupling)

$m_H = 120$ GeV

$m_H = 160$ GeV

$m_H = 200$ GeV

Independent fit of common vector and fermion couplings

$\xi_{th} = 0$

$\xi_{th} = 0.2$

$\xi_{th} = 0.6$

Not a true degeneracy

→ Each (smeared) toy experiment has unique solution

Top-associated Higgs Subjets

Add additional measurement for $t\bar{t}H$, $H \rightarrow b\bar{b}$ using subjet techniques

[Plehn, Salam, Spannowsky]

extrapolated to 7 TeV
SM hypothesis

⇒ Secondary solution strongly suppressed
→ large g_t disfavoured by new measurement
